ADDRESSES.

THE PRESIDENT'S ADDRESS.

Delivered at the Fourteenth Annual Meeting of the American Academy of Medicine, held at Philadelphia, December 3, 1890.

BY S. J. JONES, A.M., M.D., LL.D.,
OF CHICAGO, ILL.

On this interesting occasion, when we are felicitating ourselves on the re-assembling of the Academy in the place of its birth, we find added interest in the fact that it was here that the first medical college in America was organized, and that the teaching which was so well begun in Colonial days has not been allowed to lag in the onward movement of the intervening years; that here the American Medical Association completed its organization in the interest of liberal medical education and elevation of the medical profession, and its first report on medical education was made; and here, during the Centennial Medical Congress, the work of the medical profession of America for a century was portrayed, showing its achievements and its defects, and making apparent its needs.

This occasion, therefore, is of more than ordinary interest to us.

It was fitting that an organization having an object such as that of this Academy should have originated here and amid the influences which surrounded that Congress.

The founders of the Academy were inspired by the greatness of our calling, with its possibilities for good, and encouraged by the achievements of our predecessors,— often accomplished under most adverse circumstances. They were also admonished by knowledge of our shortcomings, which had been rendered apparent in the numerous formal reports on Medical Education made at the annual meetings of the American Medical Association between the years 1847 and 1873, as also, in the carefully prepared addresses delivered before the Centennial Medical Congress. Thus, with an appreciation of the difficulties of the work yet to be accomplished in fulfilling its mission, the Academy entered upon its undertaking with limited numbers but in such manner as in the state of literary and medical education, at that time, seemed best suited to remedy existing defects. As

that Centennial Congress afforded a favorable occasion for review of the work of the whole profession in the preceding century, so our return here, to-day, suggests a retrospect of the work of the Academy in the fourteen years of its existence, and it may not be unprofitable to consider, briefly, its aims and its present needs for fruitful endeavor in the future. Great and gratifying as were the results that had been accomplished by our profession in the century preceding that congress, it was apparent that much yet remained to be done, especially in the matter of preparatory education of students of medicine. Since that time such increased facilities have continually been added in their teaching, in the best equipped medical colleges, that it is within the limits of accuracy to assert that at no other time within the history of the world have such opportunities been afforded students of medicine as in the present day, and to this end the efforts of this Academy have doubtless contributed.

In order that students may be enabled to comprehend and to fully profit by such instruction, the need of proper mental discipline, before entering upon their medical studies, is so undoubted as neither to require or admit of argument, but emphasizes the importance of the Academy's mission and the usefulness of its efforts.

In its organization the fact was recognized that elevation of the medical profession must primarily rest upon liberal education, with implied mental discipline, as the foundation on which to build successfully.

Already many changes have occurred in the matter of education, literary and medical, especially since the Colonial times with the medical apprentice system and the primitive educational efforts of those earlier days.

In the rapidly shifting scenes by which we are surrounded, and in the onward march of science that characterizes the age in which we are living, it is no small undertaking to move apace with those events and to keep our educational institutions abreast of that advance, and so adjusted as to meet the demands of these progressive times.

Especially in the latter part of the present century has wonderful advance been made in science and art and the humanities. As is meet, medi-

cine, which has been called "the link that unites science and philanthropy," seeks to keep pace with those advances. Being a liberal profession as well as an art, it should ever be in the forefront in the progress of civilization. It is the aim, and it has been the effort, of the Academy to secure higher preliminary and medical education as being in the direction of further advancement of the profession whose purposes are, first to prevent conditions which lead to disease, suffering and untimely death, and, next, to alleviate disease and the suffering of our fellow men so far as it lies within the power of man to do. That the efforts of the Academy have not been unavailing in its laudable endeavor, seems apparent in the increasing numbers which are yearly being added to the roll of its fellows, and in the estimate in which it is held by the medical profession, even among those who are not eligible to fellowship under the prescribed conditions, but who indorse its aim and its work.

At the time of its organization almost the only degree conferred, at graduation, by the literary colleges of this country was that of Bachelor of Arts, and the Academy adopted that degree as offering presumptive evidence of liberal education, and made it a *sine qua non* of fellowship.

Since that time many of the prominent literary colleges of our country have modified their curricula of study, and they now confer other degrees, after a course equivalent to that which is required to obtain the degree of Bachelor of Arts.

Acting upon the recognized fact that the Academy desires not merely the possession of any particular literary degree, but such mental discipline as qualifies for profitable study of medicine, its council at its last annual meeting, after careful consideration of the subject in its many bearings, recommended that the conditions of fellowship, which required the possession of that degree received in course, be so modified that applicants giving evidence of equivalent preparatory liberal education, or having other literary degrees, conferred upon them in course, and after having completed a curriculum of study equivalent to that required for obtaining the degree of Bachelor of Arts, as determined by the Council and upon its recommendation, should be eligible to election. The Academy so amended its Constitution and placed itself *en rapport* with the progress of the immediate present, untrammelled by too conservative traditions of the past, and, on the other hand, guarding against such radical change as might lead to belief that it had abandoned the very corner stone of its foundation, and its *raison d'être*. But additional provision is needed, to enable it to meet the requirements of the near future because of the changes that are yearly being made regarding the practice of medicine.

For the last two years an effort has been in progress, through committees appointed for that purpose, to ascertain the names and addresses of all physicians in the United States who are eligible to Fellowship under the prescribed condition of having the degree of Bachelor of Arts. That work has shown that but a very small proportion were eligible; so small, in fact, that the Academy cannot with its comparatively limited Fellowship at present, nor could it, if all who were eligible by reason of possessing that degree should unite with us, become the power for good that it should be, nor exert the influence necessary to the accomplishment, at an early date, of the purpose for which it was designed.

Since its aim is that of a missionary seeking to accomplish the greatest good for mankind, it would seem to be the part of wisdom not only to persevere in the line of the good work that it has been doing, but to admit to Fellowship, immediately on graduation, all physicians who meet its literary and professional requirements, and, in addition, to widen its sphere by bringing into affiliation with it and securing the active coöperation of the better element of our profession that have not enjoyed the advantages of a literary course such as has heretofore been necessary to entitle to Fellowship, but who, without such preliminary training, have attained a useful and honorable position in our profession; men whose character and acquirements make them representative members of our calling in different sections of our country; men who, though not thus made eligible to Fellowship, are broad enough in their views not to join in the charge that has been made by some that this Academy, by restricting its conditions of Fellowship, aims to establish an illiberal mutual-admiration society, whose motto is "I am holier than thou." To us it is well known that the charge is alike groundless and unjust, but it must be admitted that among those less familiar with the Academy and its work it has not been without a degree, though perhaps slight, of influence adverse to its principles and its endeavors.

If by any proper means, as by construing liberally the present requirements for Fellowship, or by changing the conditions requisite for honorary membership, or by establishing associate fellowship, we can identify with the Academy that better element, a powerful ally in our missionary work can be, and should be, secured.

This subject is not new to the Academy, for in different forms it has been considered for several years, nor is it so old and trite that it may not be further discussed and considered, that our thoughts may be more crystallized, and so formulated that an end may be reached which is generally recognized as being desirable, if proper means of accomplishing it can be adopted. Many of these men realize the advantage that it would have been to them in their struggles to reach their

present positions in the profession, if they could have had opportunity of protracted mental discipline before beginning the study of medicine. Their greater difficulty in prosecuting their professional study; the embarrassments attending their practice in after years, and the seemingly impossible task of compensating for that defect, have made them keenly appreciative of the advantages which they were denied, and they are among the strongest advocates of the Academy's purpose. In the belief of the desirability, the importance and the advantage to our cause, of forming a union with them, at as early a time as it is feasible to accomplish it, due consideration of the subject at this meeting is respectfully urged.

With the many medical organizations, National and local, general and special, that have been created since the founding of the Academy, ample provision has been made for the presentation, elsewhere than in this Academy, of all scientific papers relating to medicine which the Fellows may desire to present, and this session seems an appropriate time for the Academy to consider whether, henceforth, it had not better restrict its efforts exclusively to missionary work, having as its mission:

1. Fostering of preliminary education, as being now, even more than ever before, indispensable for students of medicine.
2. Advocating higher medical education and upholding medical colleges which afford the greatest facilities for proper medical education, and which demand a high standard of qualification of their students, and
3. Advocating State control of the license to practice medicine, regardless of the possession of diplomas issued by medical colleges—making colleges what they should be, simply teaching bodies, thus stimulating to rivalry for the best teaching rather than for the largest classes, and affording the public better opportunity of judging of the qualifications of physicians than the present system of granting diplomas gives.

Such a course would give to the Academy a distinctive character, which would avoid its conflicting with any other organization, and would commend it, yet more fully, to the better element of our profession and to the thoughtful consideration of the laity as well.

If the voting public, the chief source from which medical legislation must be secured, can be made to understand that the medical profession is not actuated by purely personal motives, but that it, and this Academy as well, aims to secure, for the benefit of the people, men of liberal education for the physicians of our country, their sympathy will be enlisted, and their feeling of self-interest would be an impelling motive to procure such legislative enactments as are essential for the welfare of the citizen, for the protection of the health of the public, and for just appreciation of the usefulness,

the dignity, and the self-respect of the medical profession. They should be made to comprehend the fact that to that end strict requirements should be placed upon medical colleges, instead of continuance of the present reckless mode of chartering them, and that each State should establish by law a uniform, minimum, degree of professional attainment to entitle one to the right to practice medicine within its borders, regardless of the source of the knowledge—thereby securing qualified physicians and declaring, by official certificate for public registration, the standard reached in such an examination.

That "no nation can be truly great if unmindful of the sanitary condition of its citizens" is evident to all, but how best to care for its citizens is not so definitely settled in the minds of our people. The established facts of sanitary science have led to the adoption by Governments—our own among the number—of many measures designed to preserve the public health. Owing to our form of Government, which is not paternal in character, much that relates to the welfare of the people devolves upon the individual States which, under the police power that it has been judicially affirmed they have, can legislate for the protection of the citizen in matters that do not devolve upon the general Government. This includes the subject of legislation regarding conditions entitling physicians to the right to practice medicine. Already a number of the States have passed laws of this character defining, in various ways, the conditions essential to secure for physicians a right to practice, in each of those States, and establishing boards consisting, in part at least, of physicians who are charged with the duty of securing compliance with the law's requirements for the protection of the public from unqualified medical men. Under the laws of some of these States no diploma of a medical college is recognized as entitling its owner, or holder, to a right to enter upon the practice of medicine within those States. In others such right is conceded under certain declared limitations. This legislation, though of comparatively recent origin, has already made progress which augurs well for the future of the principles which this Academy advocates. It moreover, affords the Academy an extended field of usefulness through its Fellows residing in the different States.

When a uniform standard of examination of all applicants for license to practice medicine in any State is established, equal justice is done to all. No ground remains for charges of unjust discrimination against any. It is in the interest of scientific medicine, and therefore of the public, that every State should enact such laws, and it is but natural that the medical profession, because of their greater familiarity with the subject, should lead in formulating and advocating the passage of

such laws for their State as their experience and wisdom lead them to believe to be best suited to secure the health and well being of the people of their State. An efficient means to that end lies in securing for the State qualified physicians, and banishment of the unqualified.

To effect reforms organized effort is required, and the more systematically the work is done the better prospect of success attends it. Should the Academy deem it expedient to constitute the Fellows resident in each State a special committee for that State to represent it in advocating its principles, and seeking coöperation of the medical organizations of such State to secure medical legislation having in view the proper protection of the people, by requiring adequate preliminary and medical education to procure a license to practice, it seems probable that the usefulness of the Academy could be materially increased; its work rendered efficient; its aims practically realized, and the people as well as our profession be benefited. It may be assumed that the Academy was not organized solely for the benefit of the student of medicine, nor even for the welfare of the medical profession, alone, but to secure for the public well qualified physicians, the accomplishment of which would also, incidentally, redound to the credit of our profession. Therefore it would seem to be eminently proper that this Academy should advance still further in pursuit of its purpose, and give to its work this additional and practical direction, which would be in keeping with the spirit of progress which has recently been given additional impetus because the medical profession and the public alike are demanding some remedy for abuses that are attendant upon the transitional state in which the practice of medicine has been for the last several years. It is perhaps not essential that now or here it should be attempted to explain why this unfortunate state exists, but more profitable to recognize the fact of its existence and the general demand for some remedy for it. If a practicable plan can be adopted by this Academy by which it can efficiently contribute toward the accomplishment of a result so much desired, it will still further demonstrate its usefulness, and additional reason for continuance of its existence.

DR. PRENTISS at a meeting of the International Medical Congress at Berlin, related the case of a lady, æt. 25, who had thin blonde hair, and who suffered from uræmic symptoms depending on an affection of the kidneys. Frequent injections of pilocarpine were given. In one month the hair had become changed to a chestnut color, and after two months it was found to be a deep black; the hair, moreover, being much fuller and thicker than before.

ORIGINAL ARTICLES.

THE HYGIENE OF SCHOOL STUDIES.

Read before the Medical Society of the District of Columbia, November 10, 1890.

BY D. S. LAMB, M.D.,
OF WASHINGTON, D. C.

This paper lays no claim to originality. The ground has been repeatedly gone over and worked up. The territory covered by the name "School Hygiene" is large and full of details. I have chosen only the "Hygiene of School Studies." The others are of equal importance; they are all interdependent. The literature is immense, especially that of the last ten years. This inquiry represents the opinion of this country, Canada, Great Britain, France and Belgium; and it is fair to assume can hardly differ from that of other European countries.

Herbert Spencer says that success in the world depends on energy rather than information; a policy which crams with information undermines energy and defeats itself. Information rapidly acquired is rapidly lost; and the cramming method unfits the brain for healthy spontaneous work. The *acquisition* of knowledge is only part; it is the *organization* of knowledge, requiring time and thought, which is useful. Spencer also compares knowledge which is simply stored up, to so much intellectual fat; it must be intellectual muscle to be of value.

The object of education is to prepare for what is commonly called "our life work;" and the test of the value of an educational course is whether it fulfils that end. To paraphrase Spencer's words by those of another author, man must be a *good animal* to succeed in life. Abnormal use of the intellectual part leads to premature arrest of the physical. The physical, mental and moral must be developed together. If either is neglected or overworked, manhood and womanhood will be ill-balanced and defective. A normal exercise of each is reflected beneficially upon the others; a normal exercise of all improves the quality of each. Old Hippocrates said that the strength of the mind increases with that of the body.

The first requisite then of a child is to be *well*; for the child as a child; as the promise of a future man or woman; and as a coming industrial individual. There cannot be a sound mind in an unsound body.

In all countries pretending to any degree of civilization, past and present, the schoolmaster has been and is an important member of society. It has been found most convenient and satisfactory by the majority of the people to delegate at least secular education of their children to one who makes a specialty of that work, and who, inferentially, is best qualified to do it. Among the Greeks he was called *Paidagogos*, a leader of

boys; afterwards a teacher of children, boys and girls. He often walked about with his scholars in the open air, asking and answering questions. Thus they acquired knowledge and health together. The spelling of the word changed from *paid* to *ped* would suggest this custom of leading the children afoot; as if from the latin *pes, pedis*, a foot. With this in mind if I might coin a word, I would say that *sedagogue* expresses the modern custom of teaching children, while sitting. The schoolmaster sits down with his scholars in a class room, properly or improperly lighted, heated and ventilated; conducing to mental effort or mental inertia.

I question whether by less session and more motion the scholar may not acquire as much useful knowledge of men and things in less time and at less cost to health. At the same time it must not be forgotten that the disabilities under which children labor, are often due, at least in part, to faulty regulations or absence of regulations at home. The first question is as to the maximum time a child may be required or permitted to study during any one day; for the present, excluding home study. Many of the writers express the conviction that except for kindergarten work, children should not enter school before the age of 8 years; that besides acquiring a greater measure of health up to that age, and diminishing very greatly the liability to contract contagious diseases, a child will learn as much, indeed more, after that age, than if he began his school studies earlier.

From the age of 7 to 9, the maximum number of hours of daily study should not exceed three. From 9 to 12 years, not more than four. The State Medical Society of Rhode Island has expressed its opinion that three is enough. From 12 to 15 years, five to six hours. From 15 to 18 years, eight hours. These statements are based on those of Drs. Newsholme of London, Chancellor and Rohé of Baltimore. Dr. Newsholme is a graduate of the Department of Public Health of the University of London, and Health Officer of Clapham; and the author of a work on "School Hygiene," London, 1887. Dr. Rohé, of Baltimore, is the author of a "Text-Book of Hygiene," Philadelphia and London, 1890. Dr. Chancellor was and may yet be the Secretary of the Maryland Board of Health, and read a paper on "School Hygiene," published by the Board in its 7th Report, 1888.

The New York Medico-Legal Society has declared its opinion that in primary schools three hours a day of study is enough.

In England it is stated that good voluntary attention in children from 10 to 12 years of age, is exhausted by four varied lessons, requiring mental effort of half an hour each, in the forenoon, with intervals of relief. After the midday meal, the capacity of voluntary attention is gen-

erally reduced one half; and not more than two half hour lessons requiring mental effort can be given with profit. This makes three hours of actual mental work in six hours of school time.

The experience of ten to twelve thousand pupils covering twelve to fifteen years, shows that the general average school time is fully double the psychological limit of the capacity of the average child, for lessons requiring mental effort. Beyond that limit, instruction is profitless. In England there are what are called half-time schools, for children who are at work part of the day in factories, etc. They have the same curriculum as the whole or six-hour scholars. The book attainments of the three-hour scholars are fully equal to those of the six. More than that, the three-hour children get through the fourth standard or grade by the nine and a half year; while the six-hour children, with double the time devoted to the same studies, fail to get through before the ten and a half to the eleventh year. The cost of the long time schools is about double that of the short.

More than that, the half-time scholars show a greater aptitude of application, superior alertness and efficiency.

In this connection I would mention Roth's "Elements of School Hygiene," London, 1886; and especially the veteran Edwin Chadwick, the well known sanitarian, who died so recently; his book called "The Health of Nations," reviewed by Benjamin Ward Richardson; 2 vols., 1887.

The French law prescribes three hours in the morning and the same in the afternoon. The School Commission of the Academy of Medicine, Paris, reported in 1888, that in the primary schools, which are divided into three grades and include children from 6 to 13 years, those in the lowest school should have daily but three and a half hours, in the middle school four and a half, and in the upper school five and a half hours of mental work with two hours of bodily exercises. *But there should be no study at home.* The "Hygiene Scolaire" of Dr. Riant, Professor of Hygiene, Paris, 1884, is an authoritative work. The time is longer in Sweden, Denmark and Germany. I would here call attention to the article of Prof. Axel Key, of Stockholm, in the *Popular Science Monthly* for November. It is a translation of his paper read before the International Medical Congress at Berlin, 1890, subject, "School Life in Relation to Growth and Health."

Opinions differ as to the limit of daily mental work in adults. Dr. Bain, of Aberdeen, says that in that city are as hard heads and as hard workers as in any other part of Great Britain, but that four hours steady mental labor are as much as is good for them. Cuvier was usually engaged for seven hours daily in his scientific researches; but they were not of a nature to require continuous thought. Walter Scott declared that

he worked for three hours with pleasure, but beyond about four hours he worked with pain. Dr. Dally, of Paris, says that a man 20 years old cannot do intellectual work with profit beyond eight hours daily. Beyond this limit there will be fatigue, cerebral anemia or congestion, disgust and impossibility to work. Generally it is necessary to limit the time to six hours or even less.

In a conference of the Board of Health of Baltimore a few years since, Dr. Chancellor and Prof. Hill stated that their own children were being taught at home. Dr. Chancellor said that his children had begun their studies at eight years of age, at which time they scarcely knew the alphabet. From that time to the ages of 12 and 13 respectively they studied for not more than two hours daily five days in the week, and nine months in the year. They were well up in the English branches, could read, write, and speak fluently the French and German, and translated fairly Italian; were making good progress in Latin and Greek, geometry and the natural sciences.

Prof. Hill gave similar testimony. His children studied only in the morning; had begun at 8 years of age; but were quite as far advanced as school children who had begun at 5 or 6. Prof. Newell believed that with two hours in the morning and one in the afternoon, the children would learn as much and probably more than with the present arrangement.

The subject of *home studies* or preparation for school, has engaged the attention of school hygienists. Circular letter No. 26 of the State Board of Health of Pennsylvania recommends that no scholar under 12 or 13 years of age should be required to study at home. I have already quoted from the report of the Commission of the Academy of Medicine of France against home studies. M. Beurrier said that it was the evening work at home or elsewhere which was responsible for over-pressure.

Dr. Crichton-Brown, in his report of inspection of the elementary schools of London, 1884, is especially caustic in his condemnation of home studies for young children. He says the principle is bad. Even when the labor is small in quantity, it stirs up and irritates an exhausted and feeble brain, and interferes with sleep. It worries and torments the child, and prevents the relaxation and entire diversion of the current of thought which ought to follow the dismissal from school. He says it is resorted to nine times in ten because the year's work cannot be done by the scholars in the regular school hours.

Dr. Roth believes that the preparation of the lessons should be made in school hours. Newsholme is more moderate. He says that home lessons should be reduced to a minimum; should not require to be done in the evening; should rather take the form of recapitulation of work

done during the day, than break into new work. That parents can best judge whether home lessons are doing harm, and should at once inform the teacher. These lessons often leave too little time for meals and recreation.

It is not to be supposed that the school hours are devoted to continuous mental labor; or that the same subject is pursued continuously for hours together. Sustained effort in one direction is quite limited, and beyond that limit, dangerous.

As to how much of a six-hour school day should be given to mental labor and how much to manual work and recreation, opinions, as might be supposed, differ; and yet most school hygienists may be divided into two classes; namely, those who demand one-third of the time for manual work and recreation, and those who demand one-half. The latter view was taken by a unanimous vote of the Congress of the French Association for the Advancement of Science, of 1883.

For continuous mental work the maximum time should be, according to Chadwick: 5 to 7 years of age, fifteen minutes; 7 to 10 years, twenty minutes; 10 to 12 years, twenty-five minutes; 12 to 15 years, thirty minutes. Newsholme says that these limits are too restricted for higher ages and interesting subjects, but that the principle is most important. The standard of mental labor may be set at arithmetic; for the average of school children, under skilful teaching, the time should be restricted to the hours named.

The model school of Brussels has adopted a uniform system for all classes, of three-quarter hour lessons and one-quarter recreation. Lessons in the natural sciences, physics, chemistry, and mechanics never more than a half-hour. Chancellor believes that there should be a ten minutes interval at the end of every hour. He also suggests that Wednesday be the holiday instead of Saturday.

The indication is to vary the subjects of instruction from hour to hour. Thus the mechanical work of writing may be followed by object lessons and experimental lectures. Language or history, which exercises the memory, may alternate with mathematics, which exercises the reason.

The capacity of attention, though of course limited, increases with age and the growth of the body, and also with skilful teaching. Some teachers, though good students and hard workers, are unable to impart knowledge. The capacity of attention is also increased by at least one-fifth by good lighting, heating and ventilating. And the morning hours are found to be better for mental work than those of the afternoon. The alternation of physical and mental work relieves the eyes, diminishing the danger of myopia; awakes attention; preserves the strength of the body, and rests the mind.

From what has already been said, it may be

deduced that at least ten minutes of the class hour should be given up to bodily exercise in some form. And in every three consecutive school hours there should also be from fifteen to thirty minutes' recess. Newsholme also suggests a few minutes' break in the middle of a study.

Where practicable the recreation should be in the open air. In this particular teachers are not as positive as they should be. Children are permitted to remain in the school rooms and even attend to some mental work, instead of being required, if their health permit, to clothe themselves according to the season and weather, and spend the recess in the open air. For this purpose of course playgrounds are necessary, and in choosing a site for a schoolhouse, the matter of sufficient playground should be one of the first requisites.

Of the forms of manual labor, I may speak only in a general way. A carpenter's shop is the form usually adopted. It well repays the cost of any expense and labor bestowed upon it. Under the supervision of the instructor the scholars can repeat the woodwork of the building itself.

Cooking is useful, especially for girls, though not them alone, for many boys also take the instruction. Where practicable, housekeeping also. A writer of note, whose name I have forgotten, strongly recommends a model nursery, as part of the education of girls, in all finishing schools and training colleges. He calls attention to the ignorance of young married women in the management of infants, and says it is a cause of the unnecessarily high death-rate among them.

Of recreations there is a great variety. The simplest is the promenade; using the muscles of the limbs, trunk, abdomen and neck. The military drill is much recommended and extensively used. It is liked by the boys; it corrects to some extent some bodily defects; promotes a sense of duty, order, obedience to command, self-restraint, punctuality, and patience; and gives suppleness to the joints, making the action prompt and easy. It is found that the drill is more effectively and permanently taught in the infantile and juvenile period than in adolescent and adult age.

Beside the immediate benefit to the child, there is a large saving of time and expense in after life, when the grown man, with a calling in life, becomes a member of the National Guard. It has been found too that the use of firearms is more quickly and perfectly acquired by the educated than the ignorant. It is estimated that in England it costs as much to properly drill and teach and keep an ignorant farm hand as fifty school lads. Chadwick proposes that after the acquisition of the drill in the juvenile period, encouragement should be given for volunteer exercises in the use of firearms. It is believed that the mixed physical and mental training would

add one-third to the civil force of the country, and more than a third to its military power.

In England the naval drill is also used; and it can be readily understood that besides the advantages derived from the military drill, there are those obtained by the use of the muscles in climbing. The cavalry drill has been recommended for the middle and higher classes, where practicable.

Leaping, running, ball play, cricket, are other forms of recreation more or less available. And fencing is useful as developing the muscles of the trunk and limbs; and requiring great activity of mind and quickness of vision.

Singing and instrumental music are useful, charming the mind. Singing develops and strengthens the muscles of the chest; increases the breathing power of the lungs, preventing pulmonary disease to some extent; and lays the foundation of a correct modulation of the voice.

Excursions into the country are strongly recommended by writers as having many advantages. There is an opportunity to learn valuable lessons in natural history and become familiar with ordinary plants. The faculty of observation is developed, and the association of teacher and scholar awakens feelings of companionship and accord; the occasion is looked for as a time of pleasure; to be deprived of it is a punishment or misfortune. In Austria the boys are taught gardening; the grounds around the school being partly used for that purpose.

Visits to museums and other places of public interest afford a large field for useful and pleasurable instruction.

There is another most useful recreation which I have long thought should form part of the school curriculum. It is swimming. This of course includes bathing, which to some school children, is perhaps a novelty. The advantages of the teaching go without saying. The muscles are developed; the circulation and nerve power improved; there is much pleasure in the exercise; children become accustomed to the water; their fears are diminished, and many unfortunate accidents would be prevented. Newsholme strongly insists on it; also Sir Charles Reed, in his report to the Educational Council of London; Janssen, the Medical Officer of Health of Brussels, and Dr. Riant, of Paris. I do not know as a fact that any school board has adopted it as a part of the teaching; but the evident interest in the subject indicates that it will be adopted.

Many of the forms of recreation named are more or less available for girls; so that there is no good reason for their failing to develop a good physique.

Where gymnastics can be had, the Swedish system, or system of Ling, is that most highly recommended.

At this point I would call attention to what I believe to be a new feature in the recreations of children. In the *English Illustrated Magazine* for November is a short article describing how some of the public school buildings of London have been opened in the evenings from 7 to 9:30 o'clock, for the children to play; no study being allowed. The results have been gratifying. I am also told that the Boston school playgrounds were opened during the last summer for a similar purpose. This action is very desirable in cities, where otherwise the children play upon the streets.

As to the evil effects of over-pressure, that is an excess of school hours or lessons beyond the capacity of the scholar, it may be said in a general way that if a boy or girl eats heartily and sleeps well, it is scarcely possible that there is overwork. The average amount of sleep required from 4 to 7 years of age is eleven hours; 7 to 10 years, ten and a half hours; 10 to 15 years, nine to ten hours; 15 to 20 years, nine hours. This implies that the child sleeps in a well ventilated and properly heated room. It must be noted that parents are to some extent responsible for loss of sleep by their children, in permitting them to spend their evenings in amusements which detain them to a late hour and are often otherwise insanitary.

The more brain work a child does, the more food it requires. Half starved children, though attaining high standing in their classes, are apt to be small in stature and feeble of muscle. If the food is plain and wholesome, the best guide to the quantity required is the child's own appetite. The midday luncheon is better, at least in the winter time, if it can be had warm. In Paris, the Director of Education authorizes janitors to provide and sell to the children warm food. It seems to me that with a little effort, the same desirable result might be attained here.

Parents are in many cases responsible for their children attending school without breakfast and sometimes without luncheon. That these children should soon become fatigued and listless may rightly be expected.

A further test of the absence of pressure is in the increase in the weight of the child. Dr. Bowditch, of Boston, made 14,000 examinations of boys, and 11,000 of girls between the ages of 5 and 16. The yearly increase in weight of the boys was 4, 4, 5, 5, 6, 5, 7, 8, 10, 12, 14 pounds; of the girls, 3.5, 4, 4.5, 5, 5, 6.5, 9.5, 10.5, 10, 7.5, 6 pounds. Should a scholar fail to reach these averages it becomes desirable to inquire into his food, clothing, amount of sleep and exercise. If these appear to be sufficient, then whether there is mental strain.

Prof. Key, in the article mentioned, furnishes some useful information in regard to growth and weight, based on an examination of 15,000 boys

and 3,000 girls. It appears that children grow rapidly from March to July or August, with but little increase in weight; then to November gain rapidly in weight, but not much in height. From November to March, again, the growth is small.

The prevalence of myopia or nearsightedness among school children is well known. Some statistics are simply appalling; such as that 100 per cent. of students at Heidelberg are myopic; while on the contrary, Widmark's examination of school children at Stockholm, under 7 years of age, showed a total absence of myopia. The causes are well known; bad light, bad air, over-heating, unsuitable desks and benches, bad print and small type. Some form of ear disease, organic or functional, was found in 23 per cent. of 6,000 Berlin school children, and Drs. Sexton, of New York, and Percival, of Baltimore, are said to have arrived at similar results. Spinal curvature due to improperly constructed desks and seats and bad positions of body. Pulmonary consumption is said to originate frequently during school life from bad ventilation, over-heating, cold draughts, improper position of body, insufficient food and excessive mental strain. Digestive disturbances are frequent from the use of improper food, irregularity of meals and insufficient closet accommodations.

Diseases of the nervous system point more directly to over-pressure in the absence of other recognizable cause. Headaches are frequent; hysteria and imitative affections; found oftener in girls than boys. Dr. McLane Hamilton says, that over 20 per cent. of the school-children of New York City have chorea. Dr. Crichton-Brown says, that there is an increase of nearly 35 per cent. in the mortality from hydrocephalus, and the increase is in children over 5 years of age. And this, too, in face of the fact of a generally diminished mortality in children. I would refer again to Prof. Key's statistics showing large percentages of illness in school children.

Many writers advocate the appointment of Medical Inspectors of schools. There has been such a medical service in Paris since 1836. The city of Brussels is a model in this respect. The officer looks after whatever pertains to the subject of school hygiene, and makes report upon the same. In those cities also, he gives treatment to scholars who are in need. Elmira, N. Y., and Boston, each has its Medical Inspector, who not only oversees the school hygiene, but is an instructor of the teachers on the subject. The advantages of having such an officer are obvious.

Much school study is dry and dull. Effort should be made to have it pleasurable. Children come to school with cheerfulness and mirth. These may be developed and utilized for educational purposes. Over strict silence exacted in some schools is simply painful; it is the suppression of joyousness, the product of fear, and

incompatible with a healthy influence. No child can be healthily developed without gladness.

Examinations have been severely criticised by many school hygienists. Prof. Hallowell thinks that the wear and tear of examinations is very injurious, especially to girls. Chancellor says that in the last quarter of the year the pressure begins; and as a result, we have nervous prostration, fainting spells, nasal hæmorrhages, St. Vitus' dance, etc.

Dr. Crichton-Brown says that examinations, instead of being tests of school work, have been to a great extent the aim and guiding principle; and whatever educational fruits they may have yielded, they produce a large crop of nervousness. Prof. Huxley calls examinations the educational *abomination* of the present day, in that the young people are stimulated to work at high pressure by the incessant competition.

Examinations have an educational value, when well conducted; they detect weak points; they show how future efforts may be made more successful. They are, however, only means to an end, and a temptation to over-pressure. They do not show the best result of a teacher's work; his personal influence in the training of the mental and moral faculties; and the influence of an upright and consistent example. And they should be limited to the work actually done by the scholar.

The following description by Charles Dickens, of Dr. Blimber's school, will bear repetition: It "was a great hot-house in which there was a forcing apparatus constantly at work. Mental green peas were produced at Christmas and intellectual asparagus all the year round. Nature was of no consequence at all; no matter what a young gentleman was intended to bear, Dr. Blimber made him bear to order, somehow or other. This was very pleasant and ingenious, but the system of forcing was attended with the usual disadvantages; there was not the right taste to the premature productions, and they did not keep well. And people did say that the doctor had rather overdone it with young Toots, who when he had whiskers, left off having brains."

THE PSYCHOPATHIC SEQUENCES OF HEREDITARY ALCOHOLIC ENTAIL- MENT.

*Read before the Mississippi Valley Medical Association, at Louisville,
Ky., October 9th, 1890.*

BY C. H. HUGHES, M.D.,

PROFESSOR OF PSYCHIATRY AND NEUROLOGY, MARION SIMS
MEDICAL COLLEGE OF MEDICINE, LATE SUPERINTENDENT
OF THE MISSOURI STATE LUNATIC ASYLUM NO. 1, ETC.

Nothing in neuropathology is now plainer than the retrograde heredity of chronic alcoholics. The alcoholic poison interferes with the highly organized physiological movements of the psy-

chical centres, arrests and perverts the complex activities of the cerebral cortex and begins a decadent and perverted neural metamorphosis that goes on from one stage of instability to another, until the final ending of all neural instability is reached (unless fortuitously arrested) in dementia or imbecility and death, when even perverted neural force can no longer be evolved. The evolution of the cerebro-psychical centres thus arrested or perverted, ends in final dissolution and extinction of type.

The neuropathic thrall of entailed alcoholism is no new theme to neurologists. It was familiar to Benjamin Rush, and the researches of Morel in the field of neuropathic degeneracy sequent to ancestral alcoholic excess, have been so often affirmed and reaffirmed by credible medical testimony that no doubt now remains in the medical mind of the power of excessive ancestral alcoholic indulgence to pervert neuropsychic function in the descendants of victims of this vicious disease.

We need not dispute the point as to whether alcoholism is a vice or disease, for it is and it may be both or either, and whether it in the beginning be one or both its ending is always in disease, which is either the beginning or continuance of a transmitted neuropathic or neuropsychopathic heritage.

If the first generation, as Morel has observed, shows immorality, alcoholic excess and brutal degradation, the second one will usually show, as he also observed, hereditary drunkenness, maniacal attacks and general paralysis or some similar psychopathic affection. The third generation may show sobriety, but instead of the transmitted drunkenness, the hereditary neuropathic perversion will probably reveal itself as Morel saw it, in hypochondria, mania, lypemania and tendency to homicide and suicide; and we shall see in the fourth and after-coming generations feeble intelligence, stupidity, early insanity and the beginning of the end of the family in extinction.

All alienists have confirmed this observation of Morel, and the fatal heritage of chronic alcoholic toxæmia is proven upon those living within the walls of asylums for the insane the world over, and in every walk of life without, and upon the cadavers of those who have died under the power of this neurotoxic force. We no longer need the extensive clinical observations of Magnan nor the later pathological researches of Bevan Lewis for proof. The diseased arterioles, the granular degenerations of the nerve cells, pericellular and perivascular nuclei proliferation, aneurismal dilatations and exudative and indurative cerebral changes, are too familiar now to be longer doubted, and witnesses too many to be here enumerated, embracing all who have clinically studied inebriety, attest the fact that the

habitual long-continued use of alcohol as a beverage in excessive quantity in one generation makes an indelible impress upon the nerve stability of the generations that follow.

It has the undoubted power of engendering neuropathic and psychopathic conditions *directly* in the individual, besides a great number of extra-neural morbid conditions, as the oft-observed and no longer doubted delirium tremens, epilepsy, insanity and imbecility, paralysis and the neuritides of drunkards show, and the morbid entailments of alcoholic excess do not stop with the individual as we have seen. They pass over in greater force to his descendants. This is the gospel of science. These morbid endowments of the drink habit are more apparent in the drunkard's progeny, for the reason that his children come into the world dowered with less power of neurotic resistance to the depressing and perverting assaults of alcohol and its compounds upon the integrity of the ganglion cells of the cerebrum and the nervous centres of the whole cerebro-spinal axis and sympathetic system.

By reason of a better organic heritage and the greater inherent power of vital resistance, the drinking person may show but little of the inroads his alcoholic excesses are making upon the physiological soundness of his cerebro-spinal and ganglionic centres. An occasional or single epileptic seizure during a debauch, or none at all, during a life given to drink, some perversions of disposition or mental depression, or a day or two of trance following a prolonged spree once or twice in a life-time, or none of these evidences of cerebro-psychical damage may so markedly appear. (The subject of alcoholic trance is largely a subject to be treated here as its forensic merits require. On this subject we content ourselves now with a simple note: *vide finis*.)

None of these positive and more directly perceptible consequences of alcoholic damage may appear directly in the individual. He may go through life moderately full of alcohol, able to attend in a fairly good manner to the routine demands of his business, to be cut off prematurely under some slight extra organic strain (for one of his extraordinary hereditary endowment of nerve resistance), by an apoplexy—cerebral or pulmonary—which another less strongly endowed for resistance by nature, would have withstood. His ganglionic centres fail him in some vital crisis, and the "silver cord is loosed" forever.

The nerve mechanism, which never escapes in the habitual or periodic excessive drinker, but more especially in the regular so-called moderate social drinker (who never sprees, though seldom refuses when asked to drink, who takes his regular evening night cap and morning eye-opener and tri-daily appetizer) is the vaso-motor system. This failure causes the pneumonia to die from an attack of lung fever of no greater severity of

causation than that of which his non-drinking fellow in the next bed promptly recovers. He may die prematurely of an over-worked kidney or an over-taxed liver, by reason of ganglionic paralysis (and I believe that over-distension of the renal circulation from the general vascular hyperæmia of over-brain-strain and alcoholic stimulation combined, are the remote causative factors of Bright's disease), and neither he nor his friends may think that alcohol has done him harm.

But look at the drinking man's children! He may have been himself a very proper and apparently healthy citizen, beginning in early life a regular business, and having acquired and filled a regular and honorable business place in the world, and never seriously sick till the last acute illness that suddenly carries him off before his physiologically appointed time.

Why is one child an idiot or imbecile, another erratic, moody, violent, visionary, melancholic, or insane, epileptic choreic, or suddenly criminal despite the best of training and environment, especially among his latest offspring, while only the children born of his loins earlier in life, when alcoholic excess had made no organic impress upon him, are ordinarily healthy in mind and body?

The habitual disturbances of organic function—morbid physiological exaltation and reactionary morbid depression, through increased vascular relaxation and consequent capillary congestion may not materially affect the integrity of function in the matured cells of the psychical centres of the parent of sober lineage, so as to markedly modify their matured and long-established habit of acting, but in the drunkard's child who starts unstably endowed by hereditary neuropathic entailment resulting from an ancestor's alcoholic excess, the resistance power of the parent or parents in early life is not in the child's organism. He is a step lower than his father or mother, or both, if they were habitual drinkers, in the scale of organic degradation, and has in consequence feeble resistance to the assaults, not only of alcohol from within, but of adverse environments from without, and they reveal this hereditary organic degradation in erratic actions, morbid, insane and criminal conduct—conduct which in them is always the offspring in whole or in part, of disease—disease within. Their environment leads them irresistibly into crime, like the circumstances without which cause in them disease their parents had not shown, and crime their parents would have resisted. Upon them, consequently, influences without their organisms resisted by others have an overpowering force.

The drunkard's child's crime is not all his voluntary crime, nor his vice engendered disease, all disease of his own making. His father, or his father's father or mother may have deliberately

chosen that which, with all its voluntary seeming in the boy, is become to him an inexorable morbid fate, appearing as immoral conduct. "The fathers have eaten sour grapes, and the children's teeth are set on edge."

With this too cursory preliminary review of what we know of the hereditary neurotic enthrallment of alcohol, we record an interesting hypothetical case, which we will suppose to cover the facts in an important medico-legal record of entailed alcoholic disease and crime perpetrated under its fatal sway.

HYPOTHETICAL CASE.

Suppose a young man approaching his majority, naturally kind of heart, not reared in crime nor in the slums of a city's poverty quarters, but in comfortable circumstances, and fairly educated among correct people, commits an unprovoked murder of one of the dearest and nearest of his friends. In his family the following abnormal traits appear: On the maternal side a grandfather is a man of excess in eating, drinking, etc.; inebriate and melancholy, and he dies of apoplexy. An only son survives him long enough to develop inebriety and die of drink in his youth. A brother is like himself, and dies a drunkard. Sisters and cousins in varying degrees, according to environment, exhibit the same failing. A grandmother at an early age drank liquor to excess, and died prematurely in consequence of excessive drink. All the sons of the grandmother's sisters died young in consequence of drink. Of the remaining ancestry of this alcohol-tainted organism, one uncle was, from early youth, addicted to alcoholic indulgence, his thirst for drink becoming finally insatiable, and he died of delirium tremens in early manhood, after previous attacks of acute alcoholic insanity. Another uncle was also addicted from his early youth to the use of alcohol to inebriety, and final melancholia and insanity with delusions of dread and suspicion. Several sisters of these two men were victims of the hereditary failing, among them the mother of the supposed young man we are considering. The boy's father, too, was in early life, before the boy's birth, an intemperate man, and the boy himself was from early puberty intemperate, unstable and choreic, and had suffered in childhood from a physical shock to his nervous system, caused by a violent fall. This young man in question, when under the influence of liquor, was a markedly changed man, and when the time of one of his periodically recurring sprees would come around, he was likewise very different from his natural self, being moody, listless, drowsy and melancholy; and after indulging in his inordinate craving and unnatural appetite, he would become exhilarated, reckless of danger, excessively cheerful at times, and extremely violent towards, and suspicious of

his best friend, filled with morbid fears and dreads and suspicions. When sober he was nervous, restless and unhappy, and whenever he got a taste of liquor he would invariably drink to excess—drinking to exhaustion, prostration and illness in consequence of his excesses. Suppose for five or ten years the life of such a person was almost one continual succession of sprees—suppose such a man after such a life, and at the close of a several weeks' prolonged spree, takes the life of his best friend by manual violence while struggling to get money from this friend who had refused it, and with the aid of an accomplice takes money, jewelry and other valuables from his person, pawns some of the things for liquor, making no attempt to escape, and not appearing to remember or realize the enormity of the crime committed, remains in the neighborhood of the murder intoxicated until arrested, remembering the fact of the robbery, but not believing the party robbed and maltreated was dead or seriously injured.

This is a common kind of inebriate crime. This picture would answer for the ordinary portraiture of the average inebriate criminal arraigned in our courts of justice. It is of necessity so drawn as not to describe personal cases that have come under my professional care, but it is true to inebriate nature, as I have seen it all too pitifully and painfully portrayed, and will answer well for a composite picture of morbid, as contradistinguished from purely immoral inebriety and crime. The picture is not overdrawn, but is faithfully true to nature.

I have purposely put in a criminal motive in the above hypothesis that the natural semblance to crime may appear just as it appears in many cases of insanity. The inebriate and the insane person act, unless totally demented, from motive more or less apparent, but the hidden springs of human conduct in both are different from those in the rational and healthy mind. A different combination of morbid influences, ancestral and immediate, in the nervous organism of the chronic inebriate or the periodic inebriate unites with his environment in the drink-enthralled man, from that which influences and determines ordinary human conduct in sane and temperate men.

1. Assuming the above hypothetical case to be true, what would be your judgment as to the existence or non existence of hereditary alcoholic degeneracy and impairment of the brain, and the existence or non-existence of dipsomania, or involuntary and resistless impulse to drink alcoholic liquors to excess, in the case of the supposed youth, and degree of irresponsibility from drink?

2. What was the mental condition of the supposed person when he committed this unlawful deed?

3. What is the effect on the mind and on the

will of such an inherited taint, united with the state of chronic alcoholism, as in the case of such a supposed youth?

Such, with more or less completeness of specific detail, is the character of the hypothetical case and interrogatories, of late years propounded in our courts to the expert in psychiatry, for the neuropathic entailments of chronic ancestral alcoholism. Thanks to an enlightened judiciary in some of the American States, aided by the wise and judicious efforts of our medico-legal societies, inebriety has become a recognized extenuation and often complete and just excuse for crime perpetrated under its potent and often resistless morbid influence, and the following or something like them, are still the customary interrogatories propounded, *pro forma* by the counsel for the State:

1. Is it your opinion that such a supposed person was unable to distinguish between right and wrong?

Or, perchance, the more enlightened and just interrogatory like the following is offered by the State:

"Will you say that a person so affected could not tell that an act which he committed was wrong, or if conscious that it was wrong—is it your opinion that *he was incapable of resisting the impulse to commit it* by reason of disease hereditarily entailed or acquired?"

It were fortunate for the unfortunate victim of the faulty and imperiously unstable neuropathic heritage of long-continued or hereditarily transmitted alcoholic indulgence, if a wise, humane and considerate counsel and court secure such just instructions in such clear conformity with the facts of clinical observation and experience as the last interrogatory would warrant, for inebriety either in its periodic or continuous forms is a disease, as much so as the recognized and acknowledged phases of insanity, epilepsy, idiocy and imbecility it both directly and indirectly engenders, and while in considering it in its medico-legal relations, we have also to consider the accompanying factor of a once-normal volition, we have in the inebriate a mind and will, always more or less modified, perverted, deranged by disease. Alcohol being itself a directly toxic agent, in its influence on the brain and allied nervous system as well as potently poisonous to the blood itself in any considerable quantity, and especially so as all experience proves, when long continued, in excess, in either the individual or his ancestors.

It is, indeed, a strange phenomenon of the human mind in its forensic relations that an agent which the world recognizes and acknowledges as the parent of pauperism, insanity and crime, and the chief direct or indirect populator of penal, eleemosynary and correctional institutions, and the proven cause of so much disease,

misery and death, should be held responsible to the extent it is before our judicial tribunals, when the hapless and often hopeless and helpless victims of its vicious power are arraigned to answer for crime committed through its influence over their involuntarily enslaved organisms—organisms often prenatally predestined to pathological perversion (as most of the unfortunate inmates of asylums for the insane are organically predetermined to an aberrant course of life conduct), through the alcoholic excesses or other neuropathic disorders of ancestors, or through a precocious drink-craving, however engendered, whether ancestrally or self-acquired, and prematurely and excessively indulged, to the harm of the delicate machinery of the brain.

The force of physiological habit is recognized in all of our dealings with men. Why, then, should courts ignore the power of that neuropathic thralldom which alcohol undoubtedly engenders in certain individuals, to their harm and the harm of the world about them, enchaining, enslaving and perverting conduct, until the unfortunate slave of its vicious sway is no more in harmony with his natural self, unperverted by this disease, than the lawfully and justly consigned inmate of a lunatic asylum is?

The dipsomania is as surely perverted and deranged in his brain and connected nervous system as any other lunatic, and the confirmed inebriate claims our sympathy and succor and the kindly consideration of the law, because he is the victim of disease. It is for humanity and law to decide in each individual instance, however, how far on the one hand inebriety should extenuate crime, and to what extent on the other it should punish the volition that may have engendered the disease. It is a plain proposition, which admits of no doubtful interpretation, that acute alcoholism voluntarily and premeditatively induced, or even voluntarily yielded to, for the purpose of committing or shielding from crime, is as culpable as any other criminal intent, while on the other hand a diseased propensity to drink, indulged in obedience to the promptings of a resistless organic aptitude handed down from father to son, or transmitted through the womb of an alcoholized or otherwise neuropathic mother, should receive a different consideration, just as any other neuropathic heritage causing psychopathic perversion, extenuates even the most heinous of crimes in the eye of the law and in the judgment of courts.

Our ancestors in the medical profession rescued the lunatic from the neglect and violence of ignorance; let us protect and save the nerve degenerate inebriate.

NOTE.—A correspondent of the *Courrier des Etats-Unis* sends from Paris, under date of September 20, 1890, the following mention of a recent trial for homicide, committed in that city

under somewhat peculiar circumstances, and of the prompt acquittal of the accused on the ground of mental irresponsibility. We present to our readers a translation:

On April 20th last, at 11 o'clock, A.M., a cry for help was suddenly heard to proceed from a house in Park Royal Street, an apartment of which was occupied by a widow, *æt.* 27 years, named Bohringer. The neighbors met a man on the threshold of her room, who remarked: "You can enter. It is all over with her. There she is,"—at the same time pointing to the young woman, who lay stretched on the floor in a pool of blood. The victim had been struck with a finely sharpened cold chisel. After being conveyed to the hospital St. Louis, she was able to speak but a few intelligible words, and died after an agony of a few days.

The assassin, named Joseph Hahn, a widower, and the father of three children, had long paid assiduous court to the deceased, with the expectation of marriage. That he had premeditated the crime, was patent from the fact that he had hired a cutler to sharpen the chisel, the day before. It was satisfactorily shown, before the court, that Hahn was a skillful workman, that his probity was incontestable, that he adored his children, but that, when drinking, he became violent and brutal, destroying or injuring whatever was within reach.

At first sight, the tranquil face of Hahn in no way betokened insanity; but his attitude before the court and the audience was so singular as properly to raise a doubt in this regard.

The following were his replies to questions by the court:

Court. The police report represents you to be an honest man.

Hahn. Yes, I have always been honest. I have never in my life intentionally done harm to any one. But sometimes I drink too much, and then it affects my head, so that I know no longer what I do.

C. Why do you drink?

H. Because I am obliged to associate with the public in order to procure work.

C. You met the Bohringer woman in a Roquette street restaurant. Did you know that she had a lover?

H. No, I did not know it.

C. Did you propose marriage to her?

H. No; it was she who proposed it to me. We were to be married at the end of her term of mourning. We had but two months more to wait.

C. Then why did you kill her?

To this question Hahn at first replied, "I do not know;" and then, gesticulating wildly, he said, amid loud sobs, "I loved that woman as I did my eyes; she deceived me. She had an accepted lover and I did not know it. She gave me by mistake a handkerchief belonging to that lover. She had consumed my money."

Dr. Ball testified to the limited responsibility of the prisoner. "Hahn," he said, "occupies the very borderland of insanity; he is of so hysterical a temperament that he does not enjoy the full possession of his faculties."

The jury rendered a verdict of acquittal. On the reading of the verdict Hahn appeared astounded and stupefied for several minutes.

BEQUESTS TO NEW YORK HOSPITALS.—Under the will of the late Mr. D. B. Fayerweather, of New York City, several charitable institutions will be generously remembered. The Presbyterian, St. Luke's and Manhattan Eye and Ear Hospitals will fall heir to \$25,000 each, while the Mount Sinai and Woman's State Hospitals get \$10,000 each.

MEDICAL PROGRESS.

Therapeutics.

PYOKTANIN.—The literature regarding the use of these new antiseptics of Stilling-Merck is rapidly increasing, and as usual the unfavorable or doubtful results are the latest to appear. DR. LINDSTROM (*Tratch*, 1890) has treated seventeen cases of gonorrhœa with 1:2000 or 1:4000 solutions. In no case was there anything like abortive action observed. In all but four cases the discharge became more abundant and irritating. Eleven chancres were treated with pyoktanin mixed with chalk—the results were much inferior to those obtained with the use of iodoform and calomel.

WARM SUBLIMATE SOLUTIONS.—DR. AHL has found on the ground of numerous bacteriological and clinical experiments that an application of heat to sublimate solutions increases their antiseptic powers, and at the same time diminishes their poisonous and corrosive effects. His conclusions are as follows: 1. The antiseptic action of a solution is increased by heating it above 40° C. 2. A solution of 1-20,000 or even 1-10,000, heated to 40° C. may be used without danger in penetrating wounds of the lung, pleura or peritoneum. The bactericidal effect corresponds to that of a 1-500 cold solution. 3. A solution heated to above 40° stimulates the formative properties of the tissues and accelerates the healing process. On the other hand, a cold solution of 1-1,000 has less antiseptic action than a warm solution of 1-10,000, because the latter penetrates more deeply. 4. The cut surfaces unite more rapidly than when a cold solution of 1-500 has been employed, because of the absence of caustic effects. 5. Warm and weak sublimate solutions may be used with perfect safety as regards poisonous and toxic effects.—*Internat. Pharmac. General-Anz.*

Medicine.

TREATMENT OF OVARIAN CYST WITH THE INDUCED CURRENT.—NOEGGERATH (*Centralblatt für Gynäkologie*, September, 1890) gives an account of six cases in which absorption of ovarian growths was produced by the application of the Faradic current.

The basis of this treatment is expressed in the following sentences: The current employed has the character of quantity; that is, the induced power is strong, as is generally found in the best apparatus. The negative pole of the secondary current is introduced into the vagina mounted on an insulated handle and covered with a wet sponge, while the positive pole is connected with a large plate electrode covered with moist sponge and placed over the abdomen. The current should only be strong enough to be perceived by the patient, each *séance* should last from one-half to one

hour, and be repeated about three times each week.

In one case presenting adhesions, the current was broken at intervals of one second in the hope of obtaining more energetic action, and in this way to reach the larger growths. Treatment should be continued from six to eight weeks. The most favorable cases are those presenting mono- or multilocular cysts (myxadenoma) of medium size. In this class of cases the results are much more radical than in the use of the constant current in fibromata, as the tumors disappear completely. Of course, it has no effect upon malignant growths.

ACUTE EPIDEMIC BRIGHT'S DISEASE.—FIESINGER (*Gazette Médicale de Paris*) contributes a series of fourteen cases, of what he regards as an acute infectious inflammation of the kidneys. He admits the possible relation of the poison of scarlet fever to this trouble, but thinks that it is excluded from the absolute absence of that disease from the neighborhood. It is, of course, difficult to determine the infectious agent. M. Roux has obtained from the urine a bacillus similar to that found by Eberth; it proved harmless to rabbits, whether it is pathogenic for man has, of course, not been determined.

PREVENTION OF PURULENT OPHTHALMIA IN THE NEW-BORN.—This subject is perennial, it no sooner seems definitely settled than some one questions the method or results. Recently M. PUECH has (*Archives de Toxicologie*) contributed his results with both the method of Crédé and Hegar-Kohn. He attributes the trouble to some infection from the vaginal discharges of the mother. That absence of vaginal discharge constitutes such a marked exception in pregnant women makes it necessary that precautions should be taken in every instance. He has used alternately the nitrate of silver solution, one part to fifty, and the cotton pledgets saturated with a solution of sublimate. Results have been equally favorable with each method. The latter he considers the simpler and most easily used in general practice. The former recommends itself for hospital use where the risk of infection is much greater.

INFECTIOUS INFLAMMATION OF THE LUNGS.—OSTHOF (*Monatsh. Med. Wochenschr.*) reports that he observed in the prison of Zweibrücken a large number of cases of what he regards as "infectious" inflammation of the lung, but which in their general type did not differ from the ordinary forms of croupous pneumonia. Out of 307 inmates, twenty-seven were attacked and two died. The greatest proportion was furnished by the younger prisoners. The cause of the epidemic is referred by Osthof to the unhygienic condition of the quarters occupied by the young men. The

attacks were characterized by the extraordinary severity of the general symptoms, which presented the type of a severe infection.

Surgery.

TREATMENT OF HÆMORRHOIDS.—The extreme difficulty experienced in dealing with prolapsed and engorged hæmorrhoids makes anything that will deal successfully with the symptoms, pain, itching, tenesmus and contracture of the sphincter, of great importance. An operation in many cases cannot be undertaken until these symptoms subside, or the patient will often not submit to radical procedures. Under these circumstances Alvin (*La Semaine Médicale*) recommends the application of a sponge, that is mounted upon a handle and dipped in very hot water, (53 to 66° C.) to the anal region. This proceeding is repeated five or six times at each séance. He claims that under this treatment all of the troublesome symptoms cease, the tumors are gradually reduced, and if the remedy is persisted with for some weeks the tumors finally disappear, and with this comes a sensible diminution of the anal contracture.

TRAUMATIC SUPPURATION IN THE PELVIS.—The obscurity surrounding the diagnosis of these conditions is illustrated in a case reported by RÉGNIER (*Revue Médicale de L'Est*) in which a young soldier suffered a traumatic otitis of the ascending ramus of the pubes, with the development of a retro-peritoneal phlegmon. The obscure symptoms led to an exploratory opening of the abdomen, but with negative results. The patient died forty-two days after the operation.

EXTIRPATION OF THE BLADDER.—PAWLK (*Centralblatt für Gynäkologie*) describes an interesting example of this rare operation. The patient presented herself for the first time in consequence of a severe and persistent hæmaturia. Catheterization of both ureters demonstrated that the blood came from the bladder. Palpation and endoscopic examination revealed a pedunculated polypus that was removed by galvano-cautery, through an opening in the vesico-vaginal wall; later this was closed and the patient left, apparently well.

At the end of a year she again presented herself with the statement that for eight months the hæmaturia had ceased but lately had reappeared. Endoscopic examination showed numerous sessile papilloma which were declared to be malignant, as was afterwards confirmed by the microscopic examination. A few weeks later an operation was made establishing communication between the ureters and vagina. At a later operation the bladder was completely removed; first a supra-pubic incision that did not open the peritoneum was made, the bladder freed from its attachments and finally removed through a transverse incision

in the anterior vaginal wall just above the urethra. Several efforts were made to close the vagina, but they were only partially successful, a small fistula remained that allowed the urine to dribble. This the writer thinks can be closed, when a good degree of urinary continence will be secured. On the whole the operation was a great success.

HYDATID CYST OF THE SPLEEN.—CHAINTE (Revue de Chirurgie) describes an interesting case in which a laparotomy was done, followed by fixation of the spleen to the abdominal wall, drainage of the pouch, and recovery.

The patient presented himself at the Hôtel-Dieu of Lyons, suffering from severe pain in the left side and shoulder; later a smooth round tumor was found in the left flank, extending into the pelvis. The general condition of the patient was fair, but the intense pain and loss of rest had considerably reduced his flesh and strength. An examination of the urine showed nothing abnormal; the blood presented the usual proportion of red and white corpuscles; there was no evidence of malaria or other cachexie. The tumor increased in size, and three months after admission an exploratory puncture was made that evacuated about one pint of clear, slightly albuminous fluid. Microscopic examination was negative, as it did not betray any hooklets. An hour after the puncture the patient had a severe general urticaria, but no rise of temperature. Decided amelioration in the patient's condition permitted him to leave the hospital and journey to Paris, where he was admitted to the Hôtel-Dieu, where a diagnosis was made of hydatid of the left lobe of the liver, but intervention was not deemed practical. The patient returned to Lyons and attempted to resume his occupation, when the pain in arm and shoulder returned, accompanied by frequent vomiting, complete loss of appetite, and disturbed sleep. July 20, six months after the patient's first admission, an operation was made. It consisted of an incision ten centimetres in length, in the left side, over the most prominent part of the tumor. A digital exploration showed conclusively that the spleen was the organ involved. On opening the cyst a small quantity of purulent fluid escaped. The cyst was stitched to the abdominal wall and a drainage tube inserted. His condition, after the operation, was good, and one month later he left the hospital with only a slight fistula. By the following October this was completely healed, since which time the man has been in excellent health and able to follow his occupation.

The author closes with a brief description of the few published cases of hydatid of the spleen.

Gynecology.

PERSISTENCE OF THE EMBRYONAL CLOACA IN AN ADULT WOMAN.—G. SPINELLI (Revista Chir.

Clin. e Terap.) presents an instance of this rare deformity. Cases in which the bladder empties into the vagina are comparatively frequent, and again those in which the rectum communicates with the vagina, but a persistence of the embryonal cloaca involving a deficiency in both of these septa presents a subject of great interest in the development of the embryo.

G. F., 31 years of age; first menstruation at 18, accompanied by much pain, a slight discharge of pale blood for four or five months. Coitus at 15; the first approach painful, but causing no hæmorrhage. Mammæ small, flaccid and atrophic; slight depression in the hypogastric region, where upon deep palpation a small, smooth body may be felt, resembling a uterus. Mons veneris very prominent, clitoris well developed, labia majora atrophied, labia minora hypertrophied, absence of the navicular fossa and of all vestiges of a hymen. No urinary meatus or tubercle. The orifice of the vagina is funnel-shaped, ending in a folded pocket, lightly bathed with urine. Absence of the anus. The finger, resisted by a robust sphincter, penetrated the vulva with difficulty, encountering a large and intricate cavity. In the anterior wall, 3.5 centimetres above the entrance, an oval opening was found, that communicated with the bladder. The cervix was small and conical and could be felt with difficulty, owing to the complete anteversion of the uterus. In the posterior wall, 2 centimetres above the vulva, the finger entered an opening leading into the rectum.

Slight incontinence of urine in the erect posture and at the moment of falling asleep. Solid feces are readily retained, but there is some incontinence of liquid feces. The profession of the woman, that of a prostitute, indicates the state of the sexual functions.

The writer thinks that we have in this case an example of arrest of development in the second month. Absence of the anus he attributes to defect in the formation of the recto-vaginal septum and not to atresia. Absence of the hymen speaks in favor of the theory that it is but a prolongation of the vagina.

CONTRACTIONS OF THE UTERUS INDUCED BY ELECTRICITY.—AMANN (Centralblatt für Gynäkologie) has tried, in Winckel's clinic, the application of the constant current after the method of Freund. The writer had a "cupping electrode" fabricated by the same man who made that of Freund. At the time two pregnant women were in the house upon whom premature labor should be induced. The first was that of a multipara, with deformed pelvis, so that a well formed child could not be born at term. Upon examination the os would admit the end of the finger. The kathode was connected with a small sponge (diameter 2½ cm.) contained in a cupping glass.

that was, with the aid of a spirit lamp, applied to the nipple. The anode with an area of ten cm. was placed upon the abdomen just over the uterus. The current was closed three times in five minutes. One minute after the last closure a distinct labor pain came on that lasted for one-half minute. A current of seven milliamperes was employed. Several times the current was made and broken, each time causing some contractions of the uterus; in one instance a series of four contractions. The patient also had pain in the lumbar region. A small eschar was produced upon the nipple where, owing to the too strong suction of the cupping glass, the skin was brought in contact with the metal rim surrounding the sponge. Unfortunately the patient would not submit to further treatment, and the result of these first trials were negative.

A second case was that of a quadripara in the eighth month, in whom the current was employed for from one to one and one-half hours twice each day, with a current strength of fifteen milliamperes. This method was employed for five days without the slightest success, as no labor pains could be induced. The current was well borne and the patient only complained of some pain in the back and a burning feeling in the nipples. On the sixth day a catheter was introduced that rapidly induced labor. While the writer's paper was in press he employed the method in a third case, but without success.

Results, while so poor in inducing premature labor, yet they were excellent when the current was used at term in delayed labor and during labor before and after the discharge of the placenta. A primipara presented herself at the clinic for examination just at the end of gestation. The internal examination did not give the appearance of one in labor. The current was employed in a strength of from six to eight milliamperes, after the third closure a pain was induced that lasted fifty seconds. Two pains followed spontaneously after opening the current. The current was employed several times at intervals of ten minutes. The pains then became regular and more frequent. Examination at this time showed a nearly terminated first stage.

The method was employed in several cases where the pains were weak and uncertain. One, a case of consumption, another of heart failure, and a third nephritis with great oedema. In all of these cases stronger and more frequent contractions were produced; in some of them it was necessary to increase the current strength from time to time.

The current was employed in several cases to expel the placenta, the results were largely dependent upon the period when it was used. Immediately after the birth the uterus reacted but feebly to the current, and the pains were too weak to expel the placenta. One to two hours later

after muscular tonus had returned, strong contractions could be induced and the uterus would empty itself.

Obstetrics.

SECRETION OF MILK IN THE NEWBORN.—VARIOT (*Remarques sur la sécrétion lactée chez les nouveau-nés, Gazette Médicale de Paris*) has observed a mammary secretion in quite a number of children of both sexes, varying in age from three days to nine months. In two cases the secretion was obtained in sufficient amount to permit of a quantitative examination, which showed that it contained the characteristic ingredients of milk, butter, casein and lactose. Out of thirty-two infants only six were found to present no mammary secretion, though in many of the remaining cases it was very slight indeed, and in some did not present a milky appearance. The terms the author uses, while not seemingly accurate, yet show a wide variation in the character of the secretion.

The writer regrets that he is not able to enter into the immediate cause and signification of this peculiar and temporary function in the newborn.

Toxicology.

FATAL POISONING WITH MALE FERN.—An account of a case of this nature is given in the *Therapeutische Monatshefte*, in which death ensued upon the administration of two drachms of the ethereal extract of male fern, given as an anthelmintic. A child, five years and a half old, was given the amount named, within an hour and three quarters, in three doses. A portion of the tapeworm was expelled in an hour and a half; then vomiting set in, followed by somnolence, twitching, and trismus lasting ten minutes. Death took place in five hours after the last dose was given. At the necropsy there was found tuberculosis of the lungs and abdominal glands; and the unusual results from a dose of the extract, such as was given, were presumably due in part to the impaired resistance to the action of the drug incident to a physique broken by tuberculous disease.—*N. Y. Medical Journal*.

Bacteriology.

EXPERIMENTAL PERITONITIS.—WATERHOUSE (*Virchow's Archiv, Centralblatt für Klin. Med.*) in a series of twelve observations confirmed the results of Grawitz, and negated those of Pawlowsky, that a considerable quantity of a virulent culture of the staphylococcus aureus might be injected into the abdominal cavity without causing peritonitis. Also when the staphylococcus is mixed with an untried medium it causes no disturbance if the mass can be readily absorbed; the greater the difficulty of absorption the more certain the production of peritonitis. Trials were made with agar-agar, gelatine and coagulated blood, each containing the staphylococcus, and the results were positive. Pus containing the staphylococcus possessed strong pyo-

genic properties, due, the writer thinks, more to its contained chemical substances than to its microorganisms. The observation of Grawitz, that when the infection was introduced through a wound in the abdominal wall peritonitis followed was not confirmed. When the wound was penciled with turpentine an abscess was produced, but only in cases where the wound involved the peritoneum, if it extended only to that membrane and not through it, no abscess was caused. When artificial defects were produced in the peritoneum injections of the staphylococcus caused peritonitis; a similar effect was produced in animals affected with ascites. A strangulation of the intestine for some hours, similar to that produced by a hernia, invariably caused peritonitis after the injection of the staphylococcus into the abdomen or blood-vessels. The same result was reached if the coccus was injected subcutaneously, but not if it was placed in the intestine. A few observations upon man has shown that the staphylococcus may be injected under the healthy skin without danger, but that suppuration follows if the absorption is hindered or the normal conditions are altered by passive hyperæmia.

OF THE POSITIVE POLAR ACTION OF THE CONSTANT GALVANIC CURRENT ON MICROBES AND MORE PARTICULARLY ON THE BACTERIA OF ANTHRAX.—(A note presented to the Academy of Medicine, Paris, April 28, 1890, by APOSTOLI and LAGUERRIERE.) The antiseptic and microbicidal action of the galvanic current observed by one of us in 1886 has been the object of our common investigations for the last two years.

In a sealed note deposited with the Academy of Sciences August 12, 1889, we have laid down the first results of the experiments undertaken in placing the two poles at the two extremities of the same test tube containing bouillons of culture, and at short distances from each other. All our experiments have had the control of cultures and of inoculations into animals (rabbits or guinea pig). Here are our first and principal conclusions:

1. The action of the constant galvanic current on cultures is in direct rapport with the intensity of the current measured by milliamperes.

2. For a like intensity, and all other things being equal, the length of the application is of little importance. The intensity of the current remains all the time the principal factor.

3. A current of 300 milliamperes and more applied for 5 minutes kills invariably the bacteria of anthrax. The further cultivation, attempted with a culture so treated, remained sterile; the inoculation into guinea pigs without effect.

4. A current of 200 to 290 milliamperes applied for five minutes does not destroy so surely and so certainly the virulence; some guinea pigs

will still die, but in a much longer period of time, *i. e.*, more slowly, than the control animal inoculated with the culture before it was subjected to the current.

5. A current of 100 milliamperes and less after an application of thirty minutes does not destroy the virulence: an attenuation is produced which augments with the intensity of the current, and which manifests itself in this, that the animals so inoculated die a day or two later than the control animals.

Since that period we have established that these effects are independent of the thermic influence which accompanies electrolysis. And we have studied the isolated influence of the poles and of the interpolar portion of the circuit.

We can formulate the following complimentary conclusions:

1. The chlorific effects of the current can be suppressed and nevertheless the destruction or attenuation of the microbial vitality be obtained.

2. The positive polar alone destroys or attenuates the vitality of the pathogenic organisms, for whom the inter-polar action and that of the negative pole is indifferent.

3. The antiseptic action of the positive pole (in a distinct culture medium, entirely separated from the negative pole) is exercised in smaller electric doses than in the first experiments (where the two poles being contiguous attenuate their reciprocal action.)

Thus the positive pole does not destroy at 90 milliamperes applied for a period varying from nine to thirty minutes, but above that, attenuation commences and progresses gradually, to become constant with 100 to 190 milliamperes from the first five minutes.

4. The general conclusion to be arrived at from our investigations is this, that the continued current in so-called medical doses (that is, from 90 to 300 milliamperes) has no action *sui generis* on the microbial cultures in a homogenous medium, and that its unique positive polar action is limited to the development of acids and of oxygen, as we shall demonstrate in a future paper.—*Un. Medic. d. Canad.—Cincinnati Medical News.*

SALPINGITIS GONORRHOICA.—MENGE (*Centralblatt für Gynækologie*) has examined bacteriologically the contents of the tube sack in twenty-six cases of salpingitis that have been operated in Martia's clinic in Berlin. In eight cases microorganisms were found; two presenting the streptococcus pyogenes, one the staphylococcus pyogenes albus, and a third a saprophytic rod, that was cultivated upon agar-agar. One case presented a diplococcus that could be stained by Gram's method; in the remaining three cases the gonococcus of Neisser was found. In eighteen other cases the contents of the tube proved to be absolutely sterile.

In one of the cases a ruptured tube sack allowed the gonorrhoeal pus to escape into the peritoneum, and raised the question as to whether the gonococcus could cause a specific peritonitis. This has been variously answered by different writers. Bumm claims that the gonococcus only invades cylinder epithelium, and negatives the existence of such specific disease of the peritoneum; Koch says the question is still unsettled. The writer regards the position of Bumm as untenable because of the fact that gonococci have been found in the knee-joint, a sack that closely resembles the peritoneum. It is possible that in old cases, the cocci may have to a great extent lost their virulence, due to the various saprophytic germs with which they have been brought in contact, or to antiseptics, these may not be able to start a specific peritonitis while the fresh vigorous germ might prove very dangerous.

A PATHOGENIC BACILLUS IN DECOMPOSED URINE.—KROGIVS (*Sur un bacille pathogène trouvé dans les urines pathologique—La Semaine Médicale*, No. 31) has found a bacillus in the purulent urine of old cases of stricture, cystitis, and pyelonephritis, which he thinks plays an important rôle in urine infection. Out of ten cases, the bacillus, which has not yet been described, was found three times. It belongs to the rod-like forms, the length varying from 1.8 to 3.6 μ , with rounded ends. It does not produce spores, and is easily stained by the aniline colors, which are easily removed by the method of Gram. It liquefies gelatine, and gives off the ammoniacal smell peculiar to decomposed urine. Urea is rapidly changed into carbonate of ammonium and water. Pure cultures injected into the veins or peritoneum of a rabbit produced death in from two hours to a few days. With age the culture increases in virulence. After vaccination, the part is reddened, swollen, and later gangrenous, after which the dead portion is cast off, accompanied by an ammoniacal odor, fever convulsions, and coma. Sterilized filtrates obtained with a porcelain filter present the same toxic symptoms. The writer names this germ the *ureo bacillus liquefaciens sepiens*.

THE CHOLERA POISON.—THE JOURNAL has of late frequently referred both in "Progress" and editorially to the advances that have been made in isolating the peculiar toxic substances produced by certain pathogenic microorganisms. Researches of this kind have followed so rapidly of late, that it is hardly possible to keep our readers fully informed on these important topics.

WINTER and LESAGE (*Contribution à l'étude du poison cholérique, Bulletin Méd.*, No. 29) have obtained a peculiar toxic substance from bouillon cultures of the cholera bacillus. They first precipitate with sulphuric acid, redissolve in an al-

kaline liquid, precipitate again, and then dissolve the precipitate in ether. This is dried with steam over ether when it appears as oily drops that soon harden into yellow fat-like masses, insoluble in water and acid solutions, but dissolved by ether and alkaline solutions. The amount of this substance obtained from a given culture is directly dependent upon its virulence.

Small doses of this substance (0.001 to 100. grams body weight) in watery solution injected into the stomach of a guinea pig produces a chill and rigidity in from four to six hours, followed by death at the end of twenty-four. With larger doses the fall in temperature comes in one-half or one hour, and death in from twelve to twenty hours. With weaker doses a slight reaction is produced and at the end of twenty-four hours the animal is again in a normal condition. If it is examined during this period it presents typical cholera lesions. Rabbits react but slightly to intra-venous injections. The toxic substance can be recovered from the muscles, liver, kidneys and urine. Rabbits are killed only by repeated injections when they also present the typical cholera lesions. Owing to the fact that the substance is insoluble in acid, it was found that when lactic acid was given within five hours after the toxic dose, the animal was saved.

New Instruments.

A NEW NASAL DOUCHE.—E. PIUS (*Ref. Correspondenz-Blatt für Schweizer Aerzte*) describes a new form of nasal douche which he says is, in a measure, free from some of the difficulties and dangers attendant upon the use of Weber's or Politzer's instruments. It is extremely simple in construction, consisting of a flask with perforated cork containing two glass tubes, one terminating near the top of the flask, and the other extending nearly to the bottom. Both tubes are bent to a convenient angle, the longer one terminating at the external end in a bulb that readily fits the nostril. The method of using is simply to fill the flasks with liquid and then blow into the short tube, thus increasing the pressure in the flask so that the liquid is forced into the nostril back into the naso-pharynx, whence it escapes by the opposite passage. The writer claims several advantages for his instrument: first, it is cheap and easily constructed; second, it is free from the difficulty that many persons experience in using the douche; third, pressure is limited to the force exerted by the respiratory muscles; fourth, the contraction of the palate muscles, as well as the forcible elevation of the palate, tend to assist in closing the Eustachian tubes. He says that a considerable quantity of fluid (1 to 3 litres) may be comfortably blown through the nose with but little danger. In thirty patients with over 100 injections, he had never seen any unpleasant consequences.

JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No. 68 WABASH AVE.,
CHICAGO, ILLINOIS.

All members of the Association should send their Annual *Dues* to the Treasurer, Richard J. Dunglison, M.D., Lock Box 1274, Philadelphia, Pa.

LONDON OFFICE, 57 AND 59 LUDGATE HILL.

SATURDAY, JANUARY 3, 1891.

THE NEW VOLUME.

With this first number of its sixteenth volume THE JOURNAL proffers to its readers the salutations of the New Year. As the representative of the Association it stands in peculiar relationship with a large constituency. The work of your creation, it is amenable to the membership for its action and for its utterances. It cannot serve the personal or pecuniary interest of any man, house or firm. It may not speak with individuality and personality such as is warrantable where an editor speaks only for himself, and is only answerable to himself for his expressions. Happily, the legitimate purposes of medical journalism are best attained and medical science is best served, where all personalities are lost sight of, and when, in its conduct, political and ambitious purposes and pecuniary profit are not permitted to exert any disturbing influence. Its best work can be accomplished in the absence of such entangling alliances. If it shall address itself to its legitimate sphere THE JOURNAL has before it a year of most important service.

The unsolved questions which confront the medical profession were never so varied, so vital, so profound, as they are to-day. The eminent men engaged in their solution were never before so many, so cultured, or so well equipped for service. Original research and experimentation in many and varied ways will be the characteristic labor of the coming period. A most profound impression has been made upon the public mind by reason of the alleged discovery of new and most remarkable methods of cure. These,

if true, are to be verified. New methods are at hand in every department of medicine and surgery. A restless spirit of investigation is everywhere being developed. Destructive criticism follows hard upon the pathway of reckless assertion—at a time when its restrictive service was never more in need—and a larger number of attentive readers than before await the utterances of the medical press.

Our journals will be taxed to their utmost in the effort to correctly represent to the medical profession at large the results of current investigation. Bacteriological studies, and the question of the agency of microorganisms in the production of specific diseases, will more than ever command the field of medicine.

The brilliant achievements recently made in surgery must serve as an inspiration to other, and if possible better, work; not more in lines of theoretical than in those of operative procedures.

The more important specialties have won their *raison d'être*, and are here, not simply to be, but to demonstrate the greater value of their special service.

The profession is best served when the utterances of its ablest men become the common property of the world through the agency of journalism. The dissemination of knowledge and the elimination of truth from error in medical teachings is the high purpose to which the medical press is everywhere called.

To this purpose, in connection with its special service to the American Medical Association THE JOURNAL will address its earnest effort. To this end it invites to its pages the reports of the best work done either by individuals or organizations. It will seek to keep its readers well informed as to special phases of medical progress as they present themselves, not only at home, but in other lands as well. To the furtherance of its interests we feel that the membership of the Association stands peculiarly committed. A harmony of purpose is essential to the highest interests both of the Association and of its Journal. To the promotion of this end we shall also address ourselves, confident that such service will command the hearty sympathy of the members of the Association, without whose cordial cooperation THE JOURNAL can not succeed, and with which, it cannot fail.

AMERICAN ACADEMY OF MEDICINE.

The Academy, at its annual meeting, held at Philadelphia, manifested additional and practical evidence of its continued interest in the subject of liberal preparatory education of students in medicine. It showed active work, also, in the cause of higher medical education.

Acting upon a recommendation in the president's annual address, the Academy voted to confine its efforts in future exclusively to its missionary work. Other medical organizations have become so numerous since the Academy was established that ample opportunity is afforded elsewhere for the presentation of all papers on purely medical subjects. This action on the part of the Academy makes it the only medical body in this country devoted exclusively to medical missionary work. It thus acquires a distinctive character.

Beginning its efforts at the foundation for profitable medical study,—proper preliminary mental training,—it has outlined a curriculum of study which it advises as qualifying to begin the study of medicine. One of its committees has been investigating the curricula of the different literary colleges of the United States, with a view to ascertaining their relative advantages and the comparative value of the literary degrees which those colleges confer. A report made by this committee at the Academy's recent meeting showed great differences in both respects.

Other committees report, from year to year, upon subjects connected with preliminary and medical education—such as the amount of preparatory mental discipline required by the different medical colleges for matriculation of students of medicine, and their methods of determining that fact. Another committee reports each year upon the laws of the different States to determine the qualifications, professional and otherwise, of candidates for license to practice medicine where such laws exist—including the standard adopted by those States, the method of ascertaining the qualifications of applicants, the mode of enforcing the laws, requirements, penalties for violations and kindred subjects.

Having thus begun by judicious encouragement to young men to pursue such preparatory courses, and seeking to give reliable direction in their medical study, and evincing appreciation of the medical colleges which afford the best facilities for their students, the Academy, in accord-

ance with another of the president's recommendations, decided to take an additional step in advance. It will endeavor to secure, through its Fellows resident in the different States, coöperation of the medical organizations of each State looking to legal enactments of all of the States to regulate the practice of medicine by granting, hereafter, licenses to practice only on examination, and regardless of the possession of diplomas issued by medical colleges. Such enactments have a twofold effect: They make colleges, in effect, simply teaching bodies—which is their proper function—and they secure in future, for the protection of the people, physicians who are required to demonstrate to the constituted authorities of the State their qualification for the work in which they are seeking to engage, and they expose the pretensions of the unqualified. Such legislation accomplishes, by enforcing its requirements, what the Academy has been seeking to effect by other means in the interest of scientific medicine, which means interest in the health and welfare of the people of the States. Thus it becomes an instrument for conserving the material interests of the States themselves.

It is an encouraging feature of the times that some six hundred of those who are recognized as being amongst the most liberally educated of the physicians of our country are united in a voluntary effort, and proceeding, at their own expense, in an unostentatious and systematic manner in an effort to remedy recognized educational defects, and thus to elevate the profession of medicine, thereby benefiting mankind.

In such an unobtrusive manner has much of the Academy's preliminary work been done that it has attracted comparatively little attention. What has been accomplished merits recognition and commendation. Its efforts are such as should receive the cordial and energetic support of the medical profession of the whole country. Well considered and just legislation in this regard in all of the States would prove advantageous to the public and creditable to the profession which advocated and aided it. Work having such objects in view commends itself to *THE JOURNAL*.

DESERVED HONOR.—The King of Greece has named Professor Brouardel, the eminent French medical jurist, Commander of the Order of the Saviour.

MAJOR VERSUS MINOR GYNECOLOGY.

It would be regarded as a strong corroboration of the popular view as to the disagreement of medical men, if a paper recently read before the Philadelphia County Medical Society,¹ arraiging minor gynecology as a potent factor in the production of morbid conditions necessitating major gynecological operations, should find its way into the columns of the lay press. The idea deduced from it by the casual reader might be that much of this kind of operative work, performed by young and inexperienced meddlers, or by others who might be good enough operators, but not sufficiently discriminating as to times or methods, or as to personal aptitudes of the patient, would lead eventually to virtual failure, after which the sufferers would naturally seek advice and assistance from those occupying a higher plane of surgical skill and manipulative proficiency.

The inference from perusal and study of this paper was inevitable, that there are two distinct classes of gynecological practitioners: 1, those who habitually practice Emmet's operation, introduce uterine sounds, electrodes and caustics, under the least pretense, and frequently with no better plea than that they do not know what other treatment to adopt; and 2, those who rarely indulge in any of these expedients, but perform, in the surgical diseases of women, bold and intricate operations, which have been rendered necessary by the blunders, inexperience and lack of judgment of the first-mentioned class.

These are matters, however, which must be settled by the gynecologists themselves. It would be considered an act of presumption for those who are without the pale of this specialty to sit in unsolicited judgment upon the merits of the question at issue. Doubtless minor gynecology is responsible, in many instances of meddlesome surgery, for the persistence and augmentation of suffering and the postponement of the healing process; but it is a question whether the advanced surgeon may not be throwing too much discredit upon the minor gynecologist (admitting, for a moment only, the existence of two such distinct classes of surgeons), and laying too little stress upon the intensity of the original morbid condition.

There has been so much outspoken criticism of major gynecology, its boldness and apparent reck-

lessness, that a flank movement attacking minor gynecology and holding it responsible as a causal agent in the production of surgical diseases, may divert attention into another field. We are sure, however, that the writer of the paper in question was honest in his animadversions, and had no such motive in view; but we are greatly surprised that, in the discussion in the Philadelphia Society which followed its reading, some of the excellent minor gynecologists of that city, whose ability, skill and erudite touch are recognized, did not rise to the full measure of the occasion and speak a few good words of commendation of the benefits to suffering humanity sometimes derived from minor operations judiciously performed, or of condemnation of the evil effects of often ill-timed and startling surgical exploits. Certainly more might be said in defense of sensible minor gynecology than was elicited at this meeting. Perhaps on some future occasion the other side may have an opportunity to make itself heard.

THE SITUATION AT BERLIN.

There is so far but little change in affairs at Berlin, unless there be a waning subsidence of the excitement. KOCH, according to the secular press, as the recipient of an enormous mail, and the daily besetments of applicants for relief from all parts of the world, has been compelled to betake himself to the Hartz Mountains for a two weeks' vacation, leaving EWALD in command of the pressing hosts at home. Meanwhile his personal desire, as persistently iterated, is for the opportunity to investigate in other fields and to complete his arrangements with the Prussian Government for the preparation of his "lymph." He still claims no discovery of a cure, and pleads for more time to fully verify his experiments. In the trying ordeal of so dizzy a reputation he sustains himself grandly, avoids press interviews and remains the same simple, honest man of yore. So far as the situation at home is concerned, many new names are heralded in the prints of the day, many shadowy opinions are broached, some insinuations of dishonest acquisition of the "lymph," and a controversy regarding the dose as bitter as the contest between the Big-enders and Little-enders, has become somewhat of an incident—all of which prove that the East is not always the source of wisdom. Until we can fairly distin-

¹ See THE JOURNAL, p. 656, Vol. xv.

guish between voices and echoes, as well as learn to respect the physicians extra-ordinary to the public, we prefer to withhold our verdict as to the permanent results.

EDITORIAL NOTES.

POPULATION OF THE UNITED STATES.—The Census Bureau has declared the population of the United States in June, 1890, to have been 62,480,540, exclusive of white persons in the Indian Territory, Indians on reservations, and the people of Alaska. If these figures are correct, the absolute increase in the population of the country since 1880 was 12,324,757, and the percentage of increase 24.57.

FAITH CURE IN AFRICA.—Several Americans who had gone out to Africa as missionaries, depending upon miraculous aid to resist the climate, have sickened and died. They were attacked with fever, and refused to employ medical aid. The number of such cases being likely to increase, the Governor of Sierra Leone has issued a proclamation that the climatic conditions are adverse to believers in faith-cure, and that hereafter white people will be compelled when ill to accept the services of a physician.

THE HEART IN ATHLETICS.—A British surgeon states that of 5,000 decrepit or aged soldiers that have been brought under his notice, fully 80 per cent. were suffering from cardiac trouble in one form or another, due to forced exertion. He predicts that as large a percentage of the athletes of to-day will be found twenty-five years hence to be the victims of the same causes engendered by muscular strains. With regard to the effect of exercise on the prolongation of life, it may be said that there are more people living in France who have passed the age of 60 than there are in England, the home of athletic sports, and there is probably no nation in Europe more averse to muscular cultivation for its own sake than the French. Great athletes die young, and a mortality list of Oxford men who had rowed in the 'varsity races, shows that a comparatively small percentage of them lived out the allotted time.

A BILL has been introduced in the Georgia legislature to prohibit physicians and drug clerks who are addicted to the use of whiskey or opium from practicing their profession. For the first

conviction of being drunk a fine of \$200 is imposed, and for the second the license to practice is revoked.

PROPOSED LAW AGAINST HYPNOTISM.—The following legislative measure has been introduced to the Chamber of Deputies of Belgium by the Minister of Justice: Article 1. Whoever makes a public exhibition of a person hypnotized by himself, or anyone else, will be punished by imprisonment from fifteen days to six months, and with a fine of from 26 to 1,000 francs. Article 2. Whoever, not being qualified to exercise the healing art, hypnotizes a person who has not attained the full age of 18 years, or who is not sound of mind, will be punished by imprisonment from fifteen days to one year, and to a fine of from 26 to 1,000 francs, even if the hypnotized person has not been exhibited in public. Article 3. The punishment of imprisonment will be used against any person who, with a fraudulent or malicious intention, makes a hypnotized person write or sign an act stating any agreement, disposition or declaration. The same punishment will be applied to those who take advantage of agreements so attained.

IMMUNITY OF JEWS FROM TUBERCULOSIS.—Dr. G. A. Heron has just published a work on "Evidences of the Communicability of Consumption" (Longmans). He dwells upon the immunity from tuberculosis of carefully conforming Jews, whose meat is inspected in a manner which would require the rejection of the entire carcase, if any speck of tubercle were discovered. Dr. Heron believes about 4 per cent. of the animals slaughtered for food in Great Britain are more or less affected by tuberculosis. He admits there is probably no room for doubting that a complete sacrifice of the infected animals, such as would be required by the law and practice of the Jews, or even in some Gentile communities in which an inspection of meat is rigidly enforced, would become by the diminution of disease which it would bring about, a distinct source of saving to the public.

THE INSANE POOR OF NEW YORK.—The new State Hospital for the Insane at Ogdensburg, New York, has accommodations for 200 patients, but when completed will hold 1,500. It will be occupied during the current month by pauper insane drafted from the county almshouses along

the northern tier of counties. It will be known as the St. Lawrence State Hospital. The appointments have been partly filled, Dr. P. M. Wise being Medical Superintendent and Dr. J. M. Mosher, First Assistant; this class of appointments is now under the regulation of the Civil Service Commission of the State, after free competitive examination. It remains to be seen if the county authorities will obey the orders of the Lunacy Commission to transfer patients to the State Hospitals. In one county at least the superintendents of the poor seek to evade such an order by protesting that there are no funds at their command with which to meet the expenses of removal. Instead of obtaining an appropriation the matter was referred to legal counsel for the purposes of opposing the order.

ANOTHER POST-GRADUATE SCHOOL.—The medical profession of Brooklyn, N. Y., will next year have the advantage of a post-graduate hospital and school. The plans of its conductors include an institution that will in the end afford practical instruction to three hundred or more students. The college will be governed by a medical board of regents. Every branch of medicine and surgery will eventually come within the teaching programme of its faculty.

THE POST-GRADUATE MEDICAL SCHOOL OF CHICAGO has recently added to its faculty: J. Frank, M.D., and Edmund Andrews, M.D., Surgery; Stanley P. Black, M.D., Wm. E. Quine, M.D., Norman Bridge, M.D., General Medicine; W. W. Jaggard, M.D., Obstetrics and Gynecology; D. R. Brower, M.D., Neurology; J. Nevins Hyde, M.D., Frank Montgomery, M.D., Dermatology; Henry Gradle, M.D., Otology; Charles W. Purdy, M.D., Renal Diseases, and Rosa Englemann, M.D., Diseases of Children. The School has recently moved into its new building in the business centre of the city from whence the various hospitals and dispensaries can be most readily reached. The building contains a dispensary, hospital and operating rooms for clinical teaching in all departments of medicine and surgery; chemical, microscopical and experimental laboratories for the study of toxicological chemistry and urinalysis, histology, pathology including bacteriology, experimental physiology, pathology and surgery, and a dissecting room for operative work on the cadaver and living animals. An amphitheatre adapted

for lectures to large evening classes—a reading room during the day. In addition to the daily clinical instruction throughout the year the school will give four special four weeks' courses, designed to afford unusual opportunity for very complete study for clinical diagnosis, pathological diagnosis, operative surgery, the histology, physiology, pathology, and surgery of the eye, ear, nose and throat. The demand for post graduate clinical study is beyond question. The Post-Graduate Medical School provides the above special courses in exceptional completeness, believing they will be sought by many students who demand thorough work.

AN EMBRYO MEDICAL COLLEGE IN MID-CHINA.—At Hang-Chow, in mid-China, there exists a large mission hospital under the charge of Dr. Duncan Main. The Chinese appear to have no word descriptive of a hospital so the name commonly given by them to this institution is "The Universal Benevolent Healing Office," a title that is not unmerited as to the gratuitous and tireless work that is performed by its conductors. A medical class, embryo of a possible future college, is in constant training at the hospital, and last year eight of its students were graduated at the end of a five years' course, and all are setting forth, in turn, to do medical missionary work among their countrymen. An illustration, from photograph, of the present hospital shows it to be a commodious and truly handsome structure: it was erected especially for hospital purposes in 1885.

APOPLECTIFORM NEURITIS.—Recently there have been reported several cases designated under the name above given. The disease was, in every instance, limited to the brachial plexus, and was characterized by a very sudden and complete loss of sensation and motion in the arm of the affected side. This was quickly followed by wasting of the muscles, and the electrical reactions were those of degeneration. Dejerine has recently reported a case where death occurred in consequence of some pulmonary disease, and where a post-mortem examination of the brachial plexus revealed the fact of a former hæmorrhage into that plexus. This condition was not anticipated, but it very fully explains the apoplectic mode of onset, and also demonstrates that a hæmorrhage may occur into the peripheral as well as into the central nervous system.

TOPICS OF THE WEEK.

THE VENTILATION OF CHURCHES.

Nowhere have the problems of ventilation been found to be more difficult of solution than in large public buildings. We might say in regard to many if not most of these that in this particular matter bad is the best result that has been attained. It must also be admitted that the state of churches generally proves the rule above stated, but not by way of exception. We may well ask, Why is this? Surrounded with spacious windows, furnished with ventilating panes, with several doors, and with a high and arched roof, why is it that their atmosphere during times of worship is so often offensively close? In different cases we should probably find different structural deficiencies contributing to this result, with, however, the same consequence in all—defective aeration. One, if not the principal, fault in construction in many of the older buildings is the want of outlets, or of a sufficient number of them. Such openings as do exist are better fitted to act as inlets than as exits. In buildings thus constructed a change for the better would be most fittingly inaugurated by the formation of two or more large roof outlets with revolving cowls. The allotment of floor space is also an important consideration. This, however, is a rule contrived with a reasonable regard for health considerations. It is only in the event of overcrowding that all individual rights are overwhelmed in the common crush, and wholesome breathing air becomes more scarce than standing room. The gallery system, also, if adopted on any considerable scale, is open to adverse criticism. By accommodating more sitters it necessarily increases what we may call the breathing surface, while at the same time it lessens the available air space. If constructed at all, the gallery ought to be of the lightest description compatible with due stability. The correction of the evils we have thus briefly touched upon, and especially the formation of roof outlets to promote the escape of heated and impure air, will go far to obviate such occurrences as that of ladies fainting in church, which under present conditions is only too common.—*Lancet*.

THE USE AND ABUSE OF HOSPITALS.

With regard to general hospitals of large size, there is a growing feeling both within the medical profession and among practical sanitarians and administrators that they are open to many objections. In the first place, they are an unscientific anachronism, the crowding together of such a vast number of diseased persons being as much out of place in cities as intramural burial of the dead. Indeed, it is extremely likely that the germs derived from such accumulation of every form of disease are more dangerous to the community than those which, after several years, may emanate from dead bodies. There is no doubt that patients suffering from different kinds of disease, poison the air with their exhalations and, in many cases, exchange microbes, till recovery becomes difficult even for the strongest.

The second objection to large hospitals is that, for

practical purposes, the relief which they afford may be said to be indiscriminate. This feature, from its inevitable tendency to engender and foster habits of improvidence in the poorer classes, makes it stink in the nostrils of economists. I do not hesitate to say that the out-patient department in hospitals, where the patients contribute nothing towards the expense of their treatment, is the greatest pauperizing agency at present existing in this country.

The third objection to general hospitals, as at present organized, is their cruel hardship which their indiscriminate charity inflicts on the medical practitioners in their neighborhood. These men find the competition of the hospitals simply ruinous; for, however they may lower their fees, they must still be in the same position relatively to those institutions, as the gentleman who stole the raw material to make his baskets was to his rival who "conveyed" his baskets ready made.

The out-patient department is defended by the hospital authorities, on the ground that a large selection of cases is necessary for the training of medical students. This sounds very plausible, but it will not bear examination. The educational plea is only a pretext. The real reason of the laxity in admitting out-patients is the desire to make a goodly show of work in the eyes of the public, with the object—perfectly legitimate in itself—of attracting subscriptions.

The objections that have been raised to special hospitals are numerous, though careful consideration will show that, in the main, they are unfounded. The superior persons who advance these objections, ground their opposition on the alleged fact, that the special institutions draw many cases away from the general hospitals, and thus often leave insufficient material for the teaching of students. It may, however, be asked, how it is that the special hospitals attract from the older charities persons suffering from particular diseases. The obvious answer is, that the patients find that they are more quickly cured in the special hospitals. The only question, therefore, to be decided is, whether the interests of the patient or those of the teachers of the healing art are to be considered as the more weighty. I have little doubt myself, that, in the opinion of the public generally and of the subscribers to the hospitals, the welfare of the patients will take the first place.

A more practical objection to special hospitals is, that they are supposed by some people to divert subscriptions from the general hospitals. I do not believe, however, that this objection is well founded.

The bad effects of gratuitous medical relief have been abundantly shown, and it is not denied that they exist, to a very large extent, not only in London, but practically everywhere throughout the country. The time has come when the abuse must be abolished. But how is this to be done?

Aggrieved practitioners, who have had the bread taken out of their mouths by the hospitals, have sometimes said in their haste, that the out-patient department should be reformed altogether out of existence. This drastic remedy, however, would probably defeat its own object. The real remedy for the congestion of the out-

patient department is depletion. All cases, in which a genuine claim to the receipt of gratuitous hospital relief cannot be established, should be eliminated. For this purpose two things are necessary—viz., a definite water-line of poverty, above which charity is not permitted to extend, and an adequate system of inquiry to prevent imposture. The difficulties of such a system of inquiry are great. But at Manchester, in the course of a few years, a well-organized system of investigation has reduced the proportion of cases in which hospital charity is abused from 42.32 to about 6 per cent.

I approve of the Prussian law, by which all workmen are compelled to insure against sickness. The amount of insurance is $1\frac{1}{2}$ per cent. of the wages earned. Of this, one-third is defrayed by the employer, the remaining two-thirds being deducted by him from the workmen's wages before they are paid. My own plan would be that the Poor Law infirmaries, the hospitals and the provident dispensaries should be combined, so as to form one large system of eleemosynary medical relief, somewhat on the lines of the French *Assistance Publique*, under the control of which are all the hospitals and dispensaries in France. I am strongly of opinion that a small charge to out-patients at hospitals, carefully graduated according to the patient's means, would, of itself, do much to diminish the evils now existing. In the Prussian hospitals payment is universal. All sorts and conditions of patients are freely admitted, and patients are divided into three classes, according to the rate of payment.—Sir Morell Mackenzie. *The Contemporary Review*, London, October, 1890.

JENNER AND KOCH

Habent sua fata magistri; the reception and diffusion of Jenner's great discovery was different from that of Koch by all the differentiation between the close of the eighteenth and the close of the nineteenth centuries. Jenner, after twenty-one years spent in maturing and perfecting his idea, had to wait long, in those days of slow traveling and undeveloped journalism, before it became public property. Koch, on the other hand, has positively had to suffer from the feverish haste with which his "cure" has been caught up and applied. Vaccination had for years to struggle with opposition and distrust; the injection of the Koch liquid has been so promptly appreciated and put in practice that it is already sharing the reaction inseparable from too sanguine expectation. It is in Germany that the contrast in the fortunes of the two discoveries is most keenly felt, and Stricker's classic monograph on vaccination is appealed to for points of dissimilarity between the slow advance of the one and the "leaps and bounds" of the other. It was not till July, 1801, that the Prussian Medical Department, for the first time on the Continent, issued instructions to all "*Collegia Medica et Sanitatis*" to give vaccination a trial. In June, 1802, the same official authority lent its *imprimatur* to the practice, and in October of the same year the Anti-Small-pox Vaccination Institute was established at Berlin. Popular literature, sermons from the pulpit, dramatic representations, and copy-book aphor-

isms in schools, had all to be "pressed into the service" as means to awaken the public mind to the importance of vaccination. A specimen of the "*Vorschriften zum Schönschreiben*" by which the juvenile intellect was weaned from the dread of the prophylactic innovation is the following, taken from a publication at Coburg and Leipsic in the year 1805: "Ignorant and ill-disposed people, who will neither understand nor adopt what is good, have spread abroad lies of all kind against health-giving vaccination." At Magdeburg about the same time, "*The Cow-pox*," a family scene in one act, was produced and dedicated by the author, Professor Rambach, to Dr. Welper, as the "savior of his children," the piece closing with the introduction on the stage of the children in question, each with well-developed vaccination marks on his arm. By such methods had the good German public, at the beginning of the nineteenth century, to be educated out of their well-grounded dread of inoculation, and into a hearty adoption of vaccination. With Koch's discovery, on the contrary, the profession is laboring to tone down a too roseate expectancy, and thinks it has scored a point when the question has come to be asked: "At what stage of tuberculosis is cure possible?" Meanwhile Koch himself, who is in no way to blame for the unreasoning enthusiasm his discovery has evoked, continues to perfect the system which has already cost him sixteen years' work.—*Lancet*.

A TRIBUTE TO THE PROFESSION

In Fargeon's story, contributed to the Christmas number of *All the Year Round*, there is a graceful reference to the profession. Some of our best novelists have written in a similar strain: "I cannot refrain here from paying a tribute to this kind gentleman, whose life is an honor to the profession he adorns. But, indeed, in what ranks of professional labor can more unselfish kindness be found than in the ranks of those who minister to the sick? Surely there must be some beneficent influence in the work they do that humanizes and softens the heart, that makes it respond willingly and cheerfully to the appeals of those who suffer? Numberless are the instances that can be adduced of the wonderful goodness of doctors, renowned and eminent, who sacrifice their time without expectation or desire of return for the inestimable services they render. I have no hesitation in saying that, of all arts, it is the most ennobling and beautiful, and that its record of kind deeds is matchless and unapproachable. With all my heart I say, 'Heaven bless the doctors for the good they do, for the good they are enabled to do!'"

MEDICAL FEES IN RUSSIA

According to a contemporary, the Medical Council of St. Petersburg has under consideration a project to fix the fees of medical men. It is intended to divide patients into three classes, according to their pecuniary capacity; and again, to divide towns into three categories, according to population. In accordance with this classification there will be nine fees, ranging from about twenty-five cents to five dollars.

PRACTICAL NOTES.

BEEF-TEA AS A NUTRIENT.

Dr. E. B. Ward (*American Lancet*, November, 1890) vigorously condemns beef-tea as a delusion, and sums up in the following words: "Thousands of sick people have been starved to death on this diet, and I want to enter my solemn protest against it before it is everlastingly too late. What you want is the albumen and fibrin of the meat. . . . The moment you coagulate these ingredients by heat you render them practically indigestible. . . . Good milk is preferable always, but if you must give beef-tea, never boil it. Liebig says 120° F. is the highest temperature to which it should be subjected. It is not very inviting in its general aspect, but it holds in solution the ingredients that you want and which are rendered useless for a weak digestion by boiling. Liebig's plan is to add a little hydrochloric acid." He thinks good rich milk punch, however, is far preferable.

DISINFECTION OF THE HANDS.

Ball has carefully investigated the subject of disinfection of the hands, in order to establish a routine which shall be sufficiently thorough to be sure of complete sterilization even with previously infected hands, and at the same time sufficiently simple to be properly carried out by any one. His experiments show that the following method answers these requirements better than any other, and that if the details are completely carried out, all microorganisms are removed:

1. The finger-nails, whether long or short, are first freed from any visible dirt with a knife or scissors.

2. The hands and nails are then scrubbed with a nail-brush for three minutes with warm water and a potassium soap.

3. The hands are then washed for half a minute in a 3 per cent. carbolic acid solution and then in a 1-2,000 solution of corrosive sublimate.

4. Finally the places under and around the nails are rubbed with iodoform gauze, previously soaked in a 5 per cent. solution of carbolic acid. —*Boston Medical and Surgical Journal*.

THE THERMOMETER IN THE EARLY RECOGNITION OF PHLEGMASIA.

H. Stapfer (*Revista de Ciências Médicas*): Since 1874 Siredey taught that there is danger ahead if the temperature rise during the puerperal state before the fifth day, and that the peril is extreme if the breasts remain empty or subside. And Vidal says: "After long and rigorous examination we may affirm that septic mischief is always preceded by a febrile condition." But we

must not rely upon the pulse, that is influenced too much by anxiety or emotion to be trustworthy; it is the thermometer alone which will unerringly guide us in these cases. The temperature is always a little raised during the first three days, and one of 99°, rising perhaps to 100° in the evening, may hardly attract the attention of the doctor, especially as the patient feels perfectly well and the pulse is natural; but there is danger at hand, nevertheless, and unless care be taken, its source determined and removed, it may become very serious indeed. Therefore, when in attendance in these cases, never neglect the thermometer; there is no adviser so faithful, no reaction more delicate, and above all, no precursor so certain as this. —*Provincial Med. Jour.*

MENTHOL IN THE VOMITING OF PREGNANCY.

Menthol has been recommended (*Repertoire de Pharmacie*, February 10, 1890) in the treatment of the obstinate vomiting of pregnancy. One part of menthol should be dissolved in twenty parts of alcohol and thirty parts of simple syrup, one teaspoonful being given each hour. This prescription is claimed to be extremely successful in arresting nausea and vomiting. —*Therapeutic Gazette*.

LEUCORRHOEA AND BLENNORRHOEA IN WOMEN.

Dr. Luand, in *Jour. de Méd. de Paris*.

R Creolin, gtt. xxx.

Ext. fluid hydr. canad. fl. drachm ijss.

Sig. Two teaspoonfuls in a pint of warm water to be used at one injection.

As an urethral injection the following formula is used:

R Extr. fluid hydrast. canad., gtt. xxx.

Creolin, gtt. x.

Aquæ, fl. drachm vij.

Sig. Use pure as an urethral injection.

—*Archives of Gynecology*.

TREATMENT OF A "COLD" BY SALICYLATE OF SODA.

The *Memphis Medical Journal* says of this remedy: Salicylate of sodium in free doses give as satisfactory results in the treatment of "bad colds" as it does in cutting short tonsillitis. Sodii salicylatis, ʒss; syr. auranti cort., ʒss; aquæ. menth. pipér., ad. ʒiv. ℞ Sig. A dessertspoonful every three or four hours. A dose every three hours until a free specific influence of the salicylate—tinnitus aurium—is observed will so far control the symptoms that the aching of the brow, eyes, nose, etc., will cease. The sneezing and "running from the nose" will also abate and will disappear in a few days, not leaving, as is usual under other treatment, a cough, from the extension of the inflammation to the bronchial tubes.

SOCIETY PROCEEDINGS.

American Academy of Medicine.

Fourteenth Annual Meeting, held in Philadelphia, December 3 and 4, 1890.

WEDNESDAY—MORNING SESSION.

The American Academy of Medicine met at Philadelphia on Wednesday, December 3, 1890, in the hall of the College of Physicians, at 10 o'clock A.M., Dr. S. J. Jones, A.M., LL.D., President, in the Chair. In the absence of Dr. Dunglison, Secretary, from sickness, on the first day, Dr. Charles McIntire, Jr., of Easton, Pa., Assistant Secretary, acted as Secretary. The names of the following applicants for Fellowship were reported as approved by the Council, and were elected as Fellows of the Academy:

New Fellows.—Herman Kiefer, Detroit, Mich.; Grosvenor R. Trowbridge, Danville, Pa.; John Carroll Irish, Lowell, Mass.; Alfred C. Haven, Lake Forest, Ill.; Elmer Lee, Chicago, Ill.; Arthur William Hurd, Buffalo, N. Y.; Edgar D. Wing, Galesburg, Ill.; Walter Davidson Bidwell, Leavenworth, Kan.; Bennet Jason Bristol, Webster Groves, Mo.; Adolf Alt, St. Louis, Mo.; Chas. B. Mayberry, Danville, Pa.; Benj. J. Milliken, Cleveland, O.; Edwin J. Gardiner, Chicago, Ill.; James Aubrey Lippincott, Pittsburg, Pa.; W. Hubert Dunlap, Syracuse, N. Y.; Wm. H. Browning, Brooklyn, N. Y.; Nathaniel S. Cheeseman, Scotia, N. Y.; Charles R. Whitcombe, Boston, Mass.; J. J. B. Vermyne, New Bedford, Mass.; George Eben Thompson, Boston, Mass.; Henry W. Cattell, Philadelphia, Pa.; Leonidas Lemay Mial, Morris Plains, N. J.; George Fales Baker, Philadelphia, Pa.; William H. Hawkes, Washington, D. C.; E. Baldwin Gleason, Philadelphia, Pa.; Edward Southworth Fitz, South Seville, N. J.; Hans H. Sinne, Trenton, N. J.; Henry Smith Noble, Middletown, Conn.; Peter N. K. Schwenk, Philadelphia, Pa.; Walter Temple Goodale, Saco, Me.; Archibald McLaren, St. Paul, Minn.; Reynold Webb Wilcox, 660 Madison Ave., New York, N. Y.; William James Herdman, Ann Arbor, Mich.; Charles Sumner Musser, Aaronsburgh, Pa.; William Flynn, Marion, Ind.; George Mason Fosket, North Dana, Mass.; J. M. Maurer, Shamokin, Pa.; Charles Wetherill Gumbes, Oakes, Pa.; Nathaniel B. Emerson, Honolulu, Hawaiian Island; John Van Duyen, Syracuse, N. Y.; Niles Harrison Shearer, York, Pa.; Earnest Laplace, Philadelphia, Pa.; Titus Munson Coan, New York, N. Y.; Levi Ives Shoemaker, Wilkesbarre, Pa.; Woods Hutchinson, Des Moines, Iowa; William Norris Hubbard, New York, N. Y.; William Edward Conroy, Saginaw, Mich.; Ferdinand J. S. Gorgas, Baltimore, Md.; Reginald Hall Sayre, New York, N. Y.; Arthur R. Simmons, Utica, N. Y.; Hermon G. Matzinger, Buffalo, N. Y.; Johann Flintermann, Detroit, Mich.; Sylvanus Todd Lowry, San Antonio, Tex.; Daniel Lewis, New York, N. Y.; Arthur Prince, Jacksonville, Ill.; Frank Eugene Sleeper, Sabatis, Me.; Sherman Willard Boons, Presque Isle, Me.; John H. Moore, Bridgeton, N. J.

At the meeting in Chicago in 1889, an amendment to the constitution was adopted, which admits others than the possessors of the A.B. degree as Fellows, provided they furnish evidence of preliminary education equivalent to that necessary for obtaining the degree of Bachelor of Arts.

DR. MCINTIRE read a paper on *The Value of the A.B. Degree*, which showed a marked differ-

ence in the various colleges in this country in the requirements for that degree, and in the value, therefore, which it possesses as an index of the amount of educational discipline the individual is supposed to have received. This subject will be still further investigated by Dr. McIntire. An appropriation was made by the Academy for this purpose, and the paper was, on motion of Dr. Gihon, ordered to be printed as a preliminary report on the subject, and distributed to every college and medical journal.

A communication was read from Dr. Dunglison, Secretary and Treasurer of the Academy, declining re-election to those positions, on account of other important duties and positions requiring his attention.

THE PRESIDENT appointed as the Committee on Nominations Drs. A. L. Gihon, Leartus Connor, and Benjamin Lee.

DR. CONNOR proposed to amend the Constitution, Art. 3, Sec. 4, by omitting the clause "shall have had an experience of three years in the practice of medicine in one or more of its recognized departments." Thus amended, Section 4 would read, "The Fellows shall have a good moral and professional character."

DR. J. CHESTON MORRIS proposed an amendment to Article VII, "Revenue," to require annual dues of three dollars from every Fellow.

DR. JUSTIN E. EMERSON, of Detroit, chairman of the Committee on Eligible Fellows, presented his report. The action of the Academy, at the previous annual meeting, in admitting to Fellowship those who could present evidences of preliminary education equivalent to that required for the A.B. degree, gave this Committee the additional labor of discovering who were eligible, as the Committee on the Value of the Academic Degree was to report at this meeting of the Academy. The Committee on Eligible Fellows reported the nature of the labor undertaken by them and the methods adopted to obtain the names of medical men who possessed literary degrees, and to secure the coöperation of the Fellows of the Academy as to their endorsement, etc. Suggestions were made as to the best methods of carrying out the Committee's work in the coming year. The personal aid of every Fellow of the Academy in obtaining the names of eligible Fellows and recommending them to the Academy was solicited. An appropriation was made for the use of this Committee.

AFTERNOON SESSION.

When the Academy again convened at 3 o'clock P.M., Dr. Gihon, U. S. N., chairman of Committee on Publication of the Transactions, reported adversely, deeming it advisable that the Academy should rather issue a volume of important papers that had been read at various meetings strictly germane to its objects, than a volume of Transac-

tions to include all the papers of recent date only. The Committee was instructed to present a table of contents of such a volume at the next meeting.

DR. TRAILL GREEN, of Easton, Pa., read a paper entitled *The Profession's Call for a Better Preliminary Education of its Members*, which was directly in the line of the Academy's aim and work, citing illustrations, from the results of examinations by State Boards of Examiners for license to practice, making apparent great deficiencies in many thus examined.

A paper by DR. FREDERIC H. GERRISH, of Portland, Me., was read, in his absence, by the Secretary, entitled:

TITHING-MEN WANTED,

in which he referred to the custom, in olden times in New England, of annually electing certain officers, who were called tithing-men, a principal part of whose duties was to wake up the sleepers in the congregation during Divine service. With a long wand they would tap the slumberers on the head, or poke them in some easily accessible and sensitive part of the person, thus recalling the drowsy to a sense of their ghostly obligations, and keeping them in the path of salvation. He thought the President and Secretary of the Academy should be impressed with the importance of stirring up the sleepy-heads to the important objects of the Academy, in whose work they should take an active interest, that its mission might be better understood by the profession at large, and its work rendered more effectual.

THE PRESIDENT, DR. S. J. JONES, of Chicago, then delivered his Address (See page 1), which was full of important suggestions looking to the future prosperity of the Academy. The address was referred to the Council, who subsequently reported favorably to the Academy as to the matters contained in it. If carried out by the Fellows they would give increased importance and influence to the work of the Academy. The interesting discussion that followed the reading of this address showed a marked appreciation by the Fellows present of its admirable suggestions.

DR. EDWARD JACKSON, of Philadelphia, read a paper entitled

WHAT CAN BE DONE TO SAVE THE EYES DURING SCHOOL LIFE.

He stated that myopia is always a defect, almost always a concomitant and symptom of serious organic intra-ocular disease, that under unfavorable conditions it generally tends, *pari passu* with its accompanying diseases, to become progressively worse, and that these unfavorable conditions are, as things now go, more constantly furnished in school life than under any other conditions. The paper discussed the various means available to prevent the occurrence of this morbid condition, such as correction of the modes of lighting, as to location and planning of the school-

house and its seats, its methods of artificial light; the recognition and proper correction of ametropia; the confinement of the work attempted within the limits of the visual apparatus; the care of general health and nutrition, etc. Particular stress was laid on the necessity of continuous, intelligent supervision of children during school life to avoid the morbid condition referred to, and especially to the necessity of providing for the education of those whose capacity for eye-work falls temporarily or permanently below a fair general minimum.

In the evening the annual collation took place at Boldt's Restaurant, and was participated in by a large number of the Fellows. It was a novelty to have this entertainment in the eighth story, but, as remarked by one of the Fellows, it was one of the specified objects of the Academy to *elevate* the profession.

THURSDAY—MORNING SESSION.

The Academy reconvened on Thursday at 10 o'clock, and selected Washington as the next place of the annual meeting, and May 2 as the time. After electing Fellows, and receiving the Treasurer's report, and its approval by an auditing Committee, reports of committees were next in order.

DR. DUNGLISON, Secretary of the Academy, read his

ANNUAL REPORT ON LAWS REGULATING THE PRACTICE OF MEDICINE IN THE UNITED STATES AND CANADA.

After some interesting preliminary remarks on the subject, in which he quoted a number of absurd replies to questions as elicited from the experience of Boards of Medical Examiners in the various States, he read extracts from letters received by him from gentlemen directly interested in the working of these laws in all parts of the country.¹

Dr. Dunglison, Committee on Preparation of the Catalogue of Fellows and Honorary Members of the Academy, reported that circulars had been sent out since the last annual meeting, prepared exactly in accordance with the plan adopted by the Academy at the annual meeting in 1888, upon the suggestion of President F. H. Gerrish, in his annual address; and that a large amount of information had been collected. The pecuniary condition of the treasury had not, however, allowed of its publication, other important committee work of the Academy, looking to an increase of its numerical strength and to an investigation of the value of the academical degree in different literary colleges, having received the first consideration in expenditures by the Treasurer.

DR. J. CHESTON MORRIS read a paper on *Interference of Molecular Vibrations as Explanatory of*

¹ This Report will be published in full in THE JOURNAL at an early date.

the *Phenomena of Zymotic Diseases and Diseases of Nutrition*, which was of a very scientific character, and was so discussed by the Fellows, as to show the interest it elicited.

DR. GIBON proposed an amendment to Article IV of the constitution, which specifies that officers of the Academy shall be elected from those who are in attendance; the words "in attendance" to be omitted.

The Committee on Nominations made their report, which was adopted, the Secretary being instructed to cast the ballot for the election of the officers named.

OFFICERS.

President—Theophilus Parvin, A.M., M.D., LL.D., Philadelphia, Pa. Vice-Presidents—Henry M. Hurd, A.M., M.D., Baltimore, Md.; Alonzo Garcelon, A.M., M.D., Lewiston, Me.; Robert Lowry Sibbett, A.M., M.D., Carlisle, Pa.; Richard J. Dunglison, A.M., M.D., Philadelphia, Pa. Secretary—Charles McIntire, Jr., A.M., M.D., Easton, Pa. Assistant Secretary—Edgar M. Green, A.M., M.D., Easton, Pa. Treasurer—J. Cheston Morris, A.M., M.D., Philadelphia, Pa.

DR. HENRY E. DWIGHT, of Philadelphia, read a paper entitled *The Influence of the German Universities upon our Profession*, in which, after defining the characteristics of a University, he alluded to the peculiar features which distinguished the Universities of Germany. Much valuable information was given as to the Gymnasias, the Real Schools, etc., and deductions were made as to the influence throughout the world of the teachings and scientific knowledge imparted.

DR. H. M. SELL, of Allentown, Pa., supplemented this paper with some interesting remarks on the five years' curriculum of Norway and Sweden.

DR. BENJAMIN LEE, Secretary of the State Board of Health of Pennsylvania, read a paper entitled,

AN ANALYSIS OF THE STATISTICS OF 41,500 CASES OF EPIDEMIC INFLUENZA.

He referred to the recent invasion of this disease, which beginning in Europe soon visited the United States and prostrated so many thousands of the people. He considered differentially the disease under consideration and dengue, with which many had compared it. The progress of the epidemic in this country was sketched, exhibiting its universality, and the writer then outlined the nature of the work undertaken by the health authorities of Pennsylvania to secure accurate statistical accounts of the epidemic. This interesting paper concluded with the view that the morbid influence spent itself directly upon the nervous system, and more especially upon the pneumo-gastric nerve and its associated ganglia with partial implication of the spinal cord.²

DR. J. CHESTON MORRIS, of Philadelphia, read a paper on

THE PATHOLOGY OF INFLUENZA.

in which he took the ground that influenza or gripe is a paresis or partial paralysis of the pneumo-gastric nerve, depending probably upon such a change in the atmospheric ocean, at the bottom of which we live, as involves an increased expenditure of force in maintaining circulation and respiration. Hence follow the phenomena of cardiac failure and pulmonary congestion which we too often witness; or those of gastro-intestinal trouble, or of the intense neuralgia which supervene in various parts of the body. And as a logical sequence we find the best remedies are strong excito-motor stimulants—chief among these strychnine, caffeine, alcohol and ammonia. Since he adopted the above views and treated his patients with five to ten drops of tincture of nux vomica every three or four hours, he has often been surprised at the promptness with which they have rallied, and the almost unfailing success of the method. He continued the treatment for two or three weeks, then gradually abated it, or resumed it in case of relapse. He would strongly urge its adoption by his fellow practitioners, even in extreme cases, or in those of patients evidently depressed below the *par* of vital activity without well defined symptoms.

AFTERNOON SESSION.

At the afternoon session the Academy adopted the suggestions of the President's Address, all of which had been approved by the Council, that the Fellows of the Academy, in their own States, should take the initiative in

1. Continuous effort in securing liberal preliminary education.
2. Requirement of a high standard of medical attainments.
3. State control of the practice of medicine, by granting licenses to practice based on uniform examinations and disregarding diplomas issued by medical colleges.

Dr. Perry H. Millard, of Minnesota, was elected an honorary member of the Academy.

DR. DUNGLISON, Secretary, read, in the absence of its author, Dr. H. O. Marcy, of Boston, Mass., a paper entitled

THE CORONER SYSTEM IN THE UNITED STATES.

in which he examined the laws in force in Massachusetts and other States of the Union, and in foreign countries, bearing upon the duties of the coroner and his relations to the public service. He arrived at the following conclusions or suggestions:

1. To abolish the office of coroner
2. To dispense with jury service.
3. To separate the medical from the legal

² This paper will appear in full in THE JOURNAL at an early date

² This paper will appear in full in THE JOURNAL

duties in all cases involving the examination into the causes of death where crime is suspected.

4. To entrust the medical examination only to competent medical officers properly trained in their work.

5. To make the number of these medical officers as small as consistent with the proper discharge of their duties.

6. To consign all questions of law only to properly qualified legal magistrates.

7. To remove the appointment of these officers entirely from the question of political consideration; and to be based only upon their possession of the requisite and proper qualifications.

Upon some basis of this character he thought the coroner's laws should be revised, the result being that much useless expenditure of time and money would be avoided, great sorrow and anxiety prevented, and the ends of justice better served.

THE PRESIDENT-ELECT, Dr. Parvin, was then introduced by Drs. Steiner and Sibbet, who were appointed by the president for that purpose, and delivered brief and eloquent remarks on taking the chair.

Dr. J. E. Emerson, of Detroit, and Dr. J. Taber Johnson, of Washington, D. C., were appointed additional members of Council for the ensuing year. Dr. Emerson was also appointed Chairman of the Committee on Eligible Fellows; the other members of that committee to be appointed later.

Dr. Dunglison was, on motion, appointed to continue the series of Reports on Laws Regulating the Practice of Medicine, which as Secretary he had annually presented to the Academy.

The report on *Requirements for Preliminary Education in Medical Colleges*, by Dr. John H. Rauch, of the Illinois State Board of Health, was read by title, not being received in time for the meeting, but will, on motion, constitute a part of the proceedings.

On motion of Dr. J. Cheston Morris, the thanks of the Academy were tendered the retiring Secretary and Treasurer, Dr. Dunglison, for his long and faithful services to the Academy, through a series of years, and to the cause of education. The retiring President, Dr. Jones, stated that he cordially endorsed and seconded the resolution.

The Academy, after thanking the retiring president, the resident Fellows, and the press of Philadelphia for their excellent reports of the meeting, then adjourned.

THE sale of poisons in Japan is regulated by a series of new and stringent regulations. No poison can be sold for industrial purposes without any order from a professional man, stating the purpose for which it is required and the name and address of the person who gives the order.

New York Academy of Medicine.

SECTION ON ORTHOPEDIC SURGERY.

Stated Meeting, November 21, 1890.

V. P. GIBNEY, M.D., CHAIRMAN.

DR. BEELY'S APPARATUS FOR MEASURING THE THORAX.

DR. N. M. SHAFFER exhibited one of these instruments which had been presented to him while he was in Berlin, by the inventor, Dr. Beely. A somewhat similar apparatus had been called by Dr. Nebel, a kytograph. The apparatus consists of a series of narrow parallel steel bars, placed closely together, and sliding in a rectangular metal frame. Each bar terminates in a blunt point, near the end of which, on the under surface, is a metallic point or stylus. This arrangement of bars looks not unlike a huge comb. On bringing the pointed ends against the chest, or any similar object having an irregular outline, the bars adjust themselves in the frame, so that the pointed ends form an outline identical with that of the object against which they were placed. A simple cam movement then clamps them in this position. The instrument is next laid upon a piece of paper resting on a sheet of felt, and the points on the under surfaces of the bars are made to puncture the paper by passing a small roller over all the bars successively. In this way, the desired outline is recorded on paper as a series of small punctures, about one-fifth of an inch apart. When taking a tracing from a patient while standing, an erect position is secured by means of a plumb-line fastened to a belt, which is buckled around the body. In order to secure still greater accuracy, the instrument is provided with a spirit-level. The exact level at which this transverse tracing of the chest is taken, may be marked with nitrate of silver, so that tracings taken at different times may be readily compared. With the patient in the prone position, the instrument may be used; but a longitudinal tracing, as of the spinal column, with the patient erect, is not within the contemplated scope of the instrument. Dr. Shaffer said that he had made several tracings with this instrument, and he had been very favorably impressed with its action and accuracy.

DR. JOHN RIDLON said that he had seen Dr. Beely using it with the patient in the prone position, and that he had understood that its action was only satisfactory when employed in this way. At the Berlin Congress, Dr. Nebel had exhibited a much cheaper, but less accurately made instrument, constructed on the same principle. A series of round rods were placed parallel to each other, and made to slide through a large round bar. The small bars terminated in buttons, which were applied to the chest. The outline was then transferred to paper by laying the machine on the paper, and passing a pencil along the buttons.

DR. A. B. JUDSON admired the mechanical features of the instrument, but thought that such tracings of cases of lateral curvature were of little value in view of the fact that the changes in contour occurred from day to day as a result of differences in the general tone of the patient.

A CASE OF SUPPOSED EVACUATION OF A PSOAS OR LUMBAR ABSCESS THROUGH THE VAGINA.

DR. SAMUEL KETCH presented such a case. A child, 5 $\frac{3}{4}$ years of age, of healthy parentage, and having a good family history, was admitted to the hospital on October 22, 1890, with the history of a fall six or eight weeks prior to her admission. Two weeks before she was presented for examination, she was first noticed to walk peculiarly, and she complained of "pain in her feet." She was thought to be suffering from hip-joint disease by her attending physician. At the time of the examination, her general condition was fair, and there was no pain, and the motions of the hip-joint were normal, with the exception of a slight limitation of extension on the right side, when the patient was in the prone position. Close examination revealed a small kyphos in the lower lumbar region; the right hip was prominent and relatively larger, and there was a feeling of fluctuation on that side. There was a discharge of pus from the vagina. The case was of interest, both on account of the unusual mode of evacuation of the pus, and because of the symptoms which had led to the diagnosis of hip-joint disease.

DR. SHAFFER had seen the case just reported. He had met with cases where the abscesses of Pott's disease opened into the rectum, vagina, and bladder; and in one case of disease in the dorso-lumbar region, which had extended over a period of about twenty years, pus was discharged from the bladder at intervals of a few months, accompanied by the usual symptoms of acute abscess formation. The cases in which the abscess had opened in these unusual situations had all done well, and he attributed this to the valvular opening through which the pus was discharged. In one of his cases, an abscess was found pointing into the rectum, and was purposely evacuated at this point by means of a trocar. The result had been extremely satisfactory. A similarly favorable prognosis could not be given where abscesses ruptured into the lungs. He had seen several of these cases, and in one, now under observation, which he considered unique, a boy with mid-dorsal disease suffered at intervals from fever, accompanied by the expectoration of pieces of the cancellous portion of bone.

DR. R. H. SAYRE said that anatomical considerations would lead one to expect that, owing to better drainage, abscesses opening into the alimentary canal would pursue a more favorable course than those which ruptured into the lung. He recalled a case where an abscess, situated on

each side of the vertebrae, suddenly enlarged, and caused fatal asphyxia. The autopsy showed that a "saddle bag" abscess was situated at the bifurcation of the trachea.

DR. J. K. YOUNG, of Philadelphia, said that he had recently seen a case of lumbar Pott's disease, in which the abscess had been evacuated through the vagina, and also through the abdominal walls. It had pursued a favorable course.

DR. THOMAS H. MANLEY had once treated a case of abscess in the mid-dorsal region, where evacuation had occurred through the umbilicus. It made a good recovery.

DR. AGRAMONTÉ suggested that the exact condition present in Dr. Ketch's case could not be affirmed until the vaginal discharge had been examined for gonococci.

The Chairman thought that such an examination was highly important, and suggested that search should also be made for the opening through which the pus was discharged.

Dr. Ketch, in closing the discussion, said that he was aware that the report of the case was somewhat premature, and had only been presented at the request of the Chairman for clinical material. He had not been able as yet to make the examinations suggested; but the rational symptoms, and the clinical history of the case, seemed to warrant the position which he had taken. In an experience of thirteen years at the Orthopedic Dispensary, he had never before met with such a case, and had only seen one case in private practice, and in this one, Dr. L. A. Sayre had verified the condition. In this case, there was a favorable termination.

DOMESTIC CORRESPONDENCE.

LETTER FROM BALTIMORE.

The Admission of Women to the Johns Hopkins Medical School—The Historical Club—Death of Dr. John R. Quinan—Semi-Annual Meeting of the Medical and Surgical Faculty.

You have already been informed by me of the success of the movement inaugurated in this city about the first of last May, for raising a fund of \$100,000 to secure the admission of women into the Johns Hopkins Medical School upon the same terms as men. This cannot but be regarded as marking an epoch in the literary and professional advancement of women. With a courage and an aspiration which was not to be daunted by prejudice or opposition, the managers of the project, stimulated by that determined advocate of educational equality, Miss Mary Garrett, boldly knocked at the door of the most modern and advanced of American colleges, "an institution," in the language of President Stanley Hall, of Clark University, "which in the less than fifteen

years of its existence, has done a work in stimulating other institutions and in advancing the highest standards, which is, as I think all cheerfully admit, beyond comparison in the recent history of higher education in this country." The language used in the correspondence of Mrs. Henry Winter Davis, in transmitting the gift, and that of the Trustees' minute on receiving it, is significant. It is the "most advanced medical education" that is stipulated for, and the previous training must be equivalent to the "preliminary medical course prescribed for men." It is also "understood and declared" that "such preliminary training in all its facts shall be obtained in some other institution of learning devoted in whole or in part to the education of women, or by private tuition." Further, the fund is not to be immediately used, but is to be invested until with additions and interest it reaches the sum of \$500,000, which is deemed "sufficient for the establishment and maintenance of a medical school, worthy of the reputation of this University and fully sufficient as a means of complete medical instruction."

Nothing could illustrate better the high standard contemplated for the coming school, and it will effectually exclude any but a very few select individuals from entrance. The preliminary requirements will be gauged by the preliminary medical course at the University which requires three years to complete, and of which biology, chemistry and physics form the groundwork. This is one of the courses leading to the degree of A.B. At present female students are debarred from entering the Academic department of the University, and hence the minute of the Trustees provides that they shall obtain this part of their training elsewhere or by private tuition. This will add to the difficulties of the candidates, since instruction of such a high order (much higher than ordinary college graduates receive, and including thorough laboratory courses) can be obtained at only two or three institutions in the country. So that, as Professor Osler recently remarked to the writer, the training requisite for the Hopkins medical degree will really extend over seven years of study of medicine and its cognate branches. Hence, it is evident that the Hopkins' school will hardly enter into competition with the woman's medical colleges now in existence, but will stand more in the relation of a higher school for post-graduate instruction. That this is understood and appreciated by those engaged in the teaching of women is witnessed by the heartiness with which the success of the late movement has been welcomed by those who are connected with the woman's medical colleges now in operation.

We learn from a letter of President Gilman to Mrs. Davis, which appeared in the daily papers, that the advice of the University Trustees

with reference to accepting the \$100,000 on the conditions imposed was a unanimous one. With that consummate tact for which the President is famous he concludes his letter with the remark, that "it would be a noble act, a memorable event in the history of higher education, if the women of this county should complete the endowment which they have so successfully initiated." In another letter from Judge Dobbin, the President of the University Trustees, it is hoped "that the zeal of the women now interested in our behalf will continue unabated until the necessary endowment is obtained. We do not doubt that their influence and example, and the importance and necessity of the work to be accomplished, will bring to their aid our aid men blessed with abundant wealth, whose liberality will complete that permanent endowment of the school which is necessary for its present usefulness and future development."

Encouraged by these words and stimulated by the success of their first attempt, the Baltimore ladies' committee determined to prosecute their work of collecting funds to its completion. Subcommittees were appointed in Washington, Chicago and California with Mrs. President Harrison, Mrs. Potter Palmer and Mrs. Senator Hearst, respectively, at their head. An invitation was extended to the local committees to visit the hospital, and Mrs. Harrison, on their behalf accepted and named November 14, as the day of their visit. On that day a large number of distinguished women assembled at the hospital where they were received by its officers and the Trustees and presented to Mrs. Harrison. They then partook of an elegant lunch and at its close heard brief addresses from Mr. Francis T. King, President of the Hospital Trustees, Dr. Mary Putnam Jacobi, of New York, and Prof. Henry H. Hurd, Superintendent of the institution. All these addresses referred to the character of the proposed school, which they said was to be on a plane beyond anything hitherto attempted here. At their close the guests were escorted through the building and had ample opportunity to see its perfect arrangements and equipments. It is stated that the lot is ready for the buildings as soon as the requisite endowment is secured. It is on the corner directly across the street from the hospital, and is 300 feet square.

As has already been stated in this correspondence provision, was made in Johns Hopkins' will for the medical school in connection with the University, but owing to pecuniary losses and failures of investments, the funds are lacking for carrying out this part of his design. Hence the inauguration of this movement. It is said that numerous contributions, large and small, have been received since the \$100,000 was presented and that the interest is wide-spread and growing. One subscription came from 200 contributors in

Gardiner, Maine, and another of \$2,500 was sent to defray the expense of the collections.

The exercises at the Hospital were concluded in the evening by a reception at Miss Garrett's elegant residence, corner Monument and Cathedral St., which was attended by the distinguished visitors and by the *élite* of the city. By the way, Miss Garrett's great liberality in connection with this movement deserves to be known and appreciated. Recognizing the importance of making the offer to the Trustees at this time, owing to the greater likelihood of its being accepted now than later on, when she saw that the project lagged owing to the doubt in the minds of ladies as to its acceptance, she increased her subscription from \$10,000 to \$48,000, thus completing the sum of \$100,000 which was the minimum amount determined on as presentable to the Trustees. The Trustees of the Woman's Medical College of Baltimore have had occasion to experience Miss Garrett's interest and liberality in less degree on several occasions. Besides donations to their institution, which were most opportune, it was to her that the senior class of the institution have owed the enjoyment of equal privileges in the clinical advantages of the Lying-in Hospital of the University of Maryland with the undergraduates of that school.

The writer had the pleasure of attending the inaugural meeting, at the Johns Hopkins Hospital on November 10, of the "Historical Club," an association which meets monthly, and whose object is to stimulate an interest in the subject of the history of medicine and medical literature. Prof. Welch is the President, and the following papers have been presented. By Prof. Welch: 1. Introductory Remarks concerning the Study of the History of Medicine. 2. Writers and Books on the History of Medicine. By Prof. Osler: American Medical Classics. 1. A Discourse upon the Institution of Medical Schools in America, by John Morgan, Philadelphia, 1765; 2. Introductory to the Course of Clinical Instruction at the Pennsylvania Hospital, by Thomas Bond. By Prof. Kelly: Notes upon Early Gynecological Works. By Dr. John N. Mackenzie: Some Points in the Ancient History of Rhinoscopy. By Dr. Finney: Sketch of John Archer, M.B., the first Graduate in Medicine in the United States. The two meetings were well attended and the proceedings highly interesting.

I learn that the Pathological and Bacteriological Department, under Prof. Welch, is so crowded that additional accommodations have had to be provided for those attending it. Bacteriology is especially popular, nearly forty students or physicians engaged in special research, being enrolled in that division. Dr. A. C. Abbott has been sent to Berlin as the representative of the Hospital, to investigate Koch's late discoveries.

Weekly clinics are now held at the Hospital by

Professors Osler, Halstead and Kelly, to which the physicians of Baltimore and Maryland are "cordially invited." At Dr. Osler's last clinic an interesting case was presented. It was one of dysentery in which the *amœba coli* was found in both stools and sputa. This was considered to justify the diagnosis of abscess of the liver, although there were no local signs of that affection.

Dr. John R. Quinan, a well-known physician of this city, died suddenly November 11 of apoplexy. He was an ex-President of the Medical and Chirurgical Faculty of Maryland, and a local antiquarian of some note. His most important work was "The Medical Annals of Baltimore from 1608 to 1880," prepared by direction of the State Society as a memorial of the League's Centennial Anniversary of the founding of Baltimore. It is a storehouse of information relating to the profession of this State, but owing to enforced haste of publication, it abounds with errors which detract much from its value and from the credit due the author, who devoted a large amount of time and labor to its preparation.

The Medical and Chirurgical Faculty held an interesting semi-annual meeting at Cambridge, on the Eastern Shore of Maryland, on November 11 and 12. A large number of members went down on the boat from this city, but I understand the attendance and participation of the local profession was not large or encouraging. The programme was a varied and interesting one, embracing papers by Drs. Atkinson, Michael, Mackenzie, Ashby, Winslow, Earle, Merrick, Brinton, Gardner, Harlan, Preston, Woods, Chunn, Chambers, Rohé and Canfield. Under the energetic Presidency of Dr. Thos. A. Ashby the old society is showing signs of redoubled vigor; there have been large accessions lately to its membership, and several thousand dollars have been contributed towards a medical building.

We are at last to have a morgue. The City Council has appropriated \$4,000 and a site has been selected near the harbor. The building will be 18 x 40 feet and two stories high. We have long been sadly in need of such an institution.

E. F. C.

SPECIAL CORRESPONDENCE.

"The Wisdom of Koch."

To the Editor:—It seems to me that THE JOURNAL, as the official mouth-piece of the largest, and oldest, large organized body of physicians in America, should be more conservative in its utterances than appears in the current number editorially under the above caption.

In the first place, there is an objection to extravagant praise of Prof. Koch in connection with his new treatment of lupus and tuberculosis, be-

cause, as he himself admits, its value is so far an unknown quantity. The profession has in the past properly refused, and should now and in the future refuse, to endorse any method which has not had the test of time, and in numerous hands. Prof. Koch has made wonderful and valuable contributions to scientific medicine, but in this new field of endeavor, the logical outgrowth of his pathological discoveries, we must not, simply on the basis of his success in pathological research, follow him blindly. When a case of tuberculosis treated by his method, after the lapse of one year, remains well, there will be time enough to prepare the laurel crown.

In the second place, there is an objection to extravagant praise of Dr. Koch in this connection, because, disguise it as we may, it still remains disagreeably patent that the failure to tell now what the medicament is and how it is made, when apparently sufficient data have been collected to warrant its use upon the human subject, and the acceptance of a fee therefor, smacks too much of quackery. In plain terms, it is vaunting, using and selling a secret nostrum.

So long as Prof. Koch confined himself to experimental use of his new remedy upon the lower animals, or to a limited and reasonable degree, upon the human subject, *without fee*, no one would dispute his moral and legal right to keep his knowledge to himself. But when once a *fee has been accepted* for the service, and a willingness expressed to serve others on the same terms, the experimental plea must be abandoned. And in the light of rumors of extortion, and charges by those always uncharitable to medical men, that nothing will be revealed until the few interested have made fortunes, further silence not only gives rise to further suspicion of Prof. Koch's professional honesty, but casts, by inference, discredit upon the medical profession at large.

Finally, there is an objection to extravagant praise of Prof. Koch in this connection, because, outside of the question of value and outside of the suggestion of quackery, this praise gives an undesirable boom to empiricism in medicine. Only a few days ago it was estimated that two thousand physicians had already come from foreign parts to Berlin to observe Prof. Koch's treatment, and by to-day's paper I see that in spite of the poor satisfaction experienced by those already there, the list of daily arrivals shows no decrease. Think of it! Thousands of physicians—Germans, Austrians, Italians, Russians, English and Americans (and possibly those of other nations), flocking to Berlin to see Prof. Koch's treatment, scrambling for places, and offering fabulous prices for a few drops of the liquid whose composition they do not know and cannot find out! And when asked why they want it, reply, "Because Koch thinks it will cure tuberculosis!" When has the practice of medicine witnessed such a spectacle? And THE JOUR-

NAL's praise of Koch's wisdom is helping to swell this crowd!

Hitherto the great fault of American physicians in the eyes of our European brethren has been this very thing—*empiricism*. In fact, we have been charged with having a monopoly of it. Now, of course, by this concourse of all nations in Berlin, we know that this charge is false, and I submit it to you—would it not be better, in view of all this, for THE JOURNAL, instead of encouraging, to caution its supporters? commending to their careful consideration the refusal of the French customs officer to allow the passage of the remedy sent to M. Pasteur, because the Government of his country (an excellent law) prohibited the admission of such things without a declaration of their composition.

By all means let us leave the further cultivation of empiricism to our German and English brethren, now that it has sprouted so vigorously among them.

H. B. YOUNG, M.D.

Burlington, Ia., November 29, 1890.

Euphorbia Pilulifera for Asthma.

To the Editor:—Quite recently, at the suggestion of my friend Dr. E. T. Sabal, of Jacksonville, Florida, I have used the remedy above named, *euphorbia pilulifera*, for the relief of a most stubborn case of hereditary asthma, and the results are such that I feel warranted in calling the attention of the profession to it, and also making an effort to compile some statistics which will be of service to us in the future. It is a popular domestic remedy in Australia, where it is found as a common roadside weed, and has been used for the relief of coughs, colds and other like disturbances of the air-passages, but more especially in the treatment of asthma. Dr. Sabal advised me that he had used it in a number of very marked cases which had resisted the usual treatment in Florida, and he thought it might prove equally valuable in our northern climate. The only case in which I have employed it this far, is one which is developed apparently from an ordinary cold, and has proven most intractable during foggy weather, or when the relative humidity was great. Heretofore, under the treatment of other physicians, in this country and in England, and Australia, the attacks would last from one to three weeks, and even then he would require the liberal use of hypodermatics of morphine and atropine. In the course of twenty-four hours after the first symptoms appeared, the malady would be fully developed, and the patient, a young man, would be compelled to sit up until the disease had exhausted itself. With the exception of myself, all his previous attendants had used ipecac freely, and he had come to dread the attacks on account of the nausea produced by the treatment. By the cautious employment of

atropine, morphine, and nitroglycerine, and the liberal use of oxygen gas, I had succeeded in lessening the severity and shortening the period to less than a week, but the results were much less satisfactory than when euphoria was used, together with the above described combination subcutaneously. For hypodermatic use the following was employed:

R—Morphinæ sulphas, gr. 1-4.
Atropinæ sulphas, gr. 1-150.
Trinitrin, grt. 1. ℞

Sig. For subcutaneous use; for one dose.

The formula adapted for the exhibition of euphoria as follows:

R—Ext. euphorbæ pilulifera (P. D. & Co's.).
Glycerini, ʒʒ fl. oz. ij. ℞

Sig. Take one teaspoonful every three hours.

If those who have had experience with this remedy will kindly communicate the results of their observations to me, I will be glad to give them credit in the form of a collective report.

JOHN AULDE, M.D.

1910 Arch street, Philadelphia, Dec. 12, 1890.

A Correction.

To the Editor:—In the issue of THE JOURNAL containing the report of the Mississippi Valley Medical Association meeting at Louisville, referring to my paper upon "Certainty in the Diagnosis of Tuberculosis" I am quoted as saying: "The disease is void of the slightest tendency to self-limitation." This I certainly did not say, nor did Dr. Porter, of St. Louis, in his interesting paper published in the same number of THE JOURNAL, take any such extreme grounds. He called in question Flint's doctrine of self-limitation, restricting the skepticism to cases which had advanced so far that the presence of disease could be established by physical signs. It was upon a series of such cases that Flint's teaching was based. Owing to pressure of time neither Dr. Porter's paper nor mine was discussed, but in conversation with him afterward he clearly explained his position, and I think I am correct in stating it. Tuberculosis, advanced to the production of distinct subjective and objective signs is one thing; the incipient local disease, which, in many cases at least, can now be detected by skilful application of the bacteriological test, is clinically quite another. So far as experiments upon animals can throw light upon the question, there is good reason to believe in the self-limitation, and I would not like to go on record with such a sweeping statement as that quoted. I wrote as follows: "Tuberculosis is a disease which, once well under headway, is not in any marked degree, as compared with other infections, self-limited. Self-limitation is an uncertain staff upon which to lean. We can not deserve the name of workers, nor really win battles nor advance to higher fields, nor even pre-

serve our self respect, by supinely resting upon such support and awaiting a possible victory."

Respectfully,
THEODORE POTTER, M.D.
Indianapolis, Ind.

Shall The Journal be Removed to Washington?

To the Editor:—Please place my vote on the list, as in favor of THE JOURNAL remaining at Chicago.

J. C. SMITH, M.D.
Austin, Tex., December 23, 1890.

To the Editor:—About the removal of THE JOURNAL and building a house of our own; I think it advisable to do so, and would suggest Louisville, which is neither an Eastern, Western, Northern or Southern city, but truly a central one.

J. W. DAVIS, M.D.
Smyrna, Tenn., December 23, 1890.

To the Editor:—The writer's subscription (as have those for every former one) for Vol. xv of THE JOURNAL will soon be forthcoming, and for the fact above he would regret a break in the file. To the ordinary observer the proposition to remove THE JOURNAL to the Capital or elsewhere must have in its favor some occult reason or grounds, so palpable and strong are the objections. In all forms of journalism the argument for a central place of publication is vital, but in the special case of THE JOURNAL, it is tenfold stronger. The word "Association" gives the key to this statement. Surely reasons, at the present sufficient, and daily augmenting—not to mention success—would induce the common mind to think and say "THE JOURNAL is exactly where it should be." Yours truly,

H. C. MARKHAM, M.D.
Independence, Iowa, Dec. 27, 1890.

MISCELLANY.

THE MATTISON PRIZE.—With the object of advancing scientific study and settling a now mooted question, Dr. J. B. Mattison, of Brooklyn, offers a prize of \$500 for the best paper on "Opium Addiction as Related to Renal Disease," based upon these queries:

Will the habitual use of opium, in any form, produce organic renal disease?

If so, what lesion is most likely?

What is the rationale?

The contest is to be open for two years from Dec. 1, 1890, to either sex, and to any school or language. The prize paper is to belong to the American Association for the Cure of Inebriety, and to be published in a New York medical journal, *Brooklyn Medical Journal*, and *Journal of Inebriety*. Other papers presented are to be published in some leading medical journal, as their authors may select. All papers are to be in possession of the Chairman of Award Committee, on, or before January 1, 1893.

The Committee of Award will consist of Dr. Alfred L. Loomis, President N. Y. Acad. of Medicine, Chairman; Drs. H. F. Formad, Phila.; Ezra H. Wilson, Brooklyn; Geo. F. Shradly, and Jos. H. Raymond, editor *Brooklyn Medical Journal*.

GOLDEN BELT DISTRICT MEDICAL SOCIETY.—The winter meeting of the Golden Belt District Medical Society will be held in Salina, Kan., Jan. 8, 1891, for the mutual benefit and entertainment of the profession. A general invitation to members of the profession is cordially extended to be present. The following papers will be read: "Report of a few cases of Complete Perineal Lacerations," by W. S. Harvey, M.D., Salina; "Laxatives and Cathartics, and their Application," by J. F. Brewer, M.D., Minneapolis; "Report of a Surgical Case," by P. Daugherty, M.D., Junction City; "The Therapeutic Value of Rest in Affections of the Joints," by A. L. Blesh, M.D., Hope; "The Menopause; its Relation to Disease," by J. W. Felty, M.D., Abilene; "Injuries of the Eye," by G. A. Wall, M.D., Topeka.

THE NEW SURGEON-GENERAL.—Dr. Charles Sutherland has been nominated to the office of Surgeon-General by the President. He entered the Medical Service of the Army in 1852, and is the Ranking Colonel in that department. He served with distinction in the late war and was breveted Lieutenant-Colonel and Colonel for meritorious service. Since 1866 he has held the position of Assistant Medical Purveyor. His eminent ability and his efficient services render his appointment to the highest position in his department eminently befitting, and he will doubtless fulfil the duties of his new position with fidelity to the Government, and with honor to himself.

Official List of Changes in the Stations and Duties of Officers Serving in the Medical Department, U. S. Army, from December 13, 1890, to December 26, 1890.

Major Charles Smart, Surgeon, is detailed as a delegate to represent the Medical Department of the Army at the annual meeting of the American Public Health Association, to be held at Charleston, S. C., December 16 to 19, 1890. He will proceed to Charleston, accordingly, and upon the final adjournment of the Association, return to his station in this city. By direction of the Secretary of War. Par. 2, S. O. 290, A. G. O., Washington, December 12, 1890.

Capt. William O. Owen, Jr., Asst. Surgeon, now on leave of absence, will report in person, without delay, to Col. Eugene A. Carr, Sixth Cavalry, at Rapid City, S. Dak., for duty with troops in the field, and by letter to the commanding General, Dept. of Dakota. By direction of the Secretary of War. Par. 17, S. O. 291, A. G. O., Washington, December 13, 1890.

Capt. Walter Reed, Asst. Surgeon, now on duty at Baltimore, Md., will report in person, without delay, to the commanding officer, Ft. Keogh, Mont., for temporary duty at that station, and by letter to the commanding General, Dept. of Dakota. By direction of the Secretary of War. S. O. 291, A. G. O., Hdqrs. of the Army, Washington, December 13, 1890.

Capt. William Stephenson, Asst. Surgeon, is granted leave of absence for fourteen days, to take effect on or about December 20, 1890. Par. 18, S. O. 291, A. G. O., December 13, 1890.

Capt. Francis J. Ives, Asst. Surgeon, now on leave of absence, will proceed to Rapid City, S. Dak., and report in person to Col. Eugene A. Carr, Sixth Cavalry, for duty with troops in the field, relieving First Lieut. William B. Banister, Asst. Surgeon, and reporting also by letter to the commanding General, Dept. of Dakota.

By direction of the Secretary of War. Par. 18, S. O. 289, A. G. O., Washington, December 11, 1890.

Major Stevens G. Cowdrey, Surgeon, extension of leave of absence granted in S. O. 263, November 10, 1890, from this office, is further extended ten days on account of sickness. By direction of the Secretary of War. Par. 4, S. O. 293, A. G. O., December 16, 1890.

Capt. Marcus E. Taylor, Asst. Surgeon, par. 17, S. O. 287, December 9, 1890, from this office, relating to him, is so amended as to direct him to report to the commanding officer, Vancouver Bks., Wash., for duty as post surgeon, relieving Col. Barnard D. Irwin, Surgeon, of that duty. Capt. Rudolph G. Ebert, Asst. Surgeon, will be relieved from duty at Vancouver Bks., Wash., upon the arrival of Capt. Taylor, and will then proceed to Ft. Huachuca, A. T., and report in person to the commanding officer of that post for duty. Washington, December 17, 1890.

First Lieut. Thomas U. Raymond, Asst. Surgeon, having been ordered to temporary duty at Vancouver Bks., Wash., by the commanding General, Dept. of the Columbia, is assigned to duty at that post, and relieved from further duty at Ft. Sherman, Idaho. S. O. 294, A. G. O., Washington, December 17, 1890.

Capt. Robert J. Gibson, Asst. Surgeon, now on leave of absence, will report in person, without delay, to the commanding officer, Ft. Meade, S. Dak., for duty with the Seventeenth Infantry in the field, reporting by letter to the commanding General, Dept. of Dakota. By direction of the Secretary of War. Par. 6, S. O. 297, A. G. O., Washington, December 20, 1890.

Capt. John J. Cochran, Asst. Surgeon, is granted leave of absence for six months on surgeon's certificate of disability, with permission to leave the Dept. of Texas. By direction of the Secretary of War. Par. 2, S. O. 298, A. G. O., December 22, 1890.

First Lieut. Freeman V. Walker, Asst. Surgeon, leave of absence granted in S. O. 85, Dept. Platte, November 11, 1890, is extended one month. By direction of the Secretary of War. Par. 9, S. O. 298, A. G. O., December 22, 1890.

Official List of Changes in the Medical Corps of the U. S. Navy for the Week Ending December 20, 1890.

Asst. Surgeon Sheldon G. Evans, ordered to Naval Academy, Annapolis, Md.

P. A. Surgeon Corbin J. Decker, detached from Naval Academy, and ordered to Naval Hospital, Philadelphia, Pa.

Official List of Changes of Stations and Duties of Medical Officers of the U. S. Marine-Hospital Service, for the Two Weeks Ending December 20, 1890.

Surgeon Walter Wyman, granted leave of absence for twenty days. December 11, 1890. To attend meeting of American Public Health Association. December 12, 1890.

Surgeon W. H. Long, granted leave of absence for seven days. December 20, 1890.

Surgeon R. D. Murray, granted leave of absence for thirty days. December 20, 1890.

Surgeon Fairfax Irwin, detailed for special temporary duty at M.-H. Bureau. December 10, 1890.

P. A. Surgeon H. R. Carter, to attend meeting of American Public Health Association. December 11, 1890.

P. A. Surgeon Eugene Wasdin, to attend meeting of American Public Health Association. December 11, 1890.

P. A. Surgeon J. J. Kinyoun, granted leave of absence for thirty days, with permission to go abroad. December 11, 1890.

Asst. Surgeon H. D. Geddings, upon expiration of leave to proceed to New York, N. Y., for temporary duty. December 18, 1890.

SOME DISPUTED POINTS IN THE CORRECTION OF REFRACTION ERRORS.

Read in the Section of Ophthalmology at the Forty-first Annual Meeting of the American Medical Association, at Nashville, Tenn., May, 1890.

BY B. ALEX. RANDALL, A.M., M.D.,

OPHTHALMIC AND AURAL SURGEON TO THE EPISCOPAL AND CHILDREN'S HOSPITALS, PHILADELPHIA.

In the entire range of ophthalmology there is probably no question as important as that of how to deal with errors of refraction. The sum total of discomfort, disease and impaired vision fairly ascribable to ametropia, is unapproachable by that due to any of the grave disorders to which the eye is subject; and glasses are being prescribed with ever-increasing frequency and by a rapidly widening circle of medical men. Yet it is very unfortunate to note the wide divergence in the views of men who ought to be authorities in such matters; and the acrimonious criticism with which some of them assail the work of others, attacking them even before the laity with a vigor which ill accords with professional, or even common courtesy, and can be justified only by scientific demonstrations, as yet lacking, that the treatment thus condemned is unwise and harmful.

As there are many whose views in this matter are not very definite, I have felt that in placing on record the conclusions that I have reached in ten years of close and conscientious study, I may perhaps aid some in reaching clearer views and more satisfactory results. Without claiming any originality, then, but apologizing to those who may be bored by this retravelling of much-trodden paths, I will touch upon some of the points in dispute.

First, as to the frequency of ametropia. There are probably few now remaining who will uphold the old view that the majority of people are emmetropic. The investigations of the eyes of infants and school-children have proven beyond any reasonable doubt that the young human eye is almost invariably hypermetropic, that astigmatism is extremely common, although not always easily uncovered, and that myopia—the bugbear of our German cousins especially—is almost in-

variably developed during the school age.¹ But from this point wide divergence begins. The rule that has been proven for children, is quite generally held to be inapplicable to adults. It is considered entirely natural that the immature child should present the undeveloped type of eye; but also that he should outgrow it later, as he does many other childish things. The general existence of emmetropia in adult life is claimed upon this *a priori* ground, and has really been but rarely questioned; yet it needs only a rational questioning of the view to show that it is baseless. Hardly one cornea in twenty is free from measurable astigmatism, as the modern handy ophthalmometers clearly show (Javal, Nordenson, Schiotz, Burnett, *et al*). So, too, as to axial ametropia, the few investigations made among adults, falling far short of the whole truth as they generally do, still show that not one-half could be looked on as emmetropic. Incomplete as the demonstration is, it is quite enough to throw the burden of proof upon those who would maintain the *a priori* view. Thus, it has been demonstrated by Seggel that among the common soldiers in Munich, 40 per cent. of the 3,052 eyes studied had *manifest* hypermetropia, and only 46 per cent. appeared emmetropic; yet these were healthy young adults from among whom all notably abnormal had been excluded by the enlistment examination. Stricter study would have greatly reduced this group of apparent emmetropes, just as Roosa² found among 20 eyes carefully selected as free from manifest hypermetropia only 6 which were actually emmetropic under atropia—the rest revealing hypermetropia of .65 to 1.5 D. In a study of the eyes of medical students, I found with the test glasses, among 142 eyes, 51 apparently emmetropic, 54 myopic, and only 37 with manifest hypermetropia; yet the ophthalmoscope and other methods proved that full 92 were hypermetropic, only 19 myopic, and at most 31 emmetropic.³ Of the 51 eyes which rejected convex glasses and seemed emmetropic, only 16 appeared so by other tests; and the use of a mydiatic would have reduced even this list nearly to the vanishing point. Only

¹ Randall, "The Refraction of the Human Eye," Amer. Jour. Med. Sciences, July, 1888.

² Trans. Am. Oph. Society, 1878.

³ Randall, "Eyes of Medical Students," Trans. Pennsylvania State Med. Soc. 1885.

32, or 18.8 per cent. of the total 180 eyes examined could be regarded as free from ametropia, manifest even to the incomplete investigation.

So, too, the refraction work in our clinics gives a showing of the ametropia that can be robbed of little of its force by the claim that eye patients do not fairly represent the general population. One-third of the work done at the Wills Eye Hospital in Philadelphia among its 10,000 annual patients, is the correction of refraction errors; and the proportion is nearly one-half in the Eye Clinic of the University of Pennsylvania. Let it be shown by competent investigation that any large group of adults presents a considerable proportion of emmetropia, and then only will such facts as these be at all in need of confirmation. If we look at any group of people whose refraction has been measured in order to seek the relation of refraction error to other disease—be it chorea, epilepsy, glaucoma or anything else—we find results that vary only with the method and care of the examiner. Dr. de Schweinitz found, as did Stevens, a high proportion of ametropia among choreic children, but not more than Risley found in 1,200 of the general school population of Philadelphia. In the latter investigation the emmetropes remained practically unvarying in the ages from 6 to 21 years. The study of adults reaches parallel results.

Those who would uphold the assumption of the prevalence of emmetropia, must fall back upon a series of unproven and really untenable explanations of why the facts conflict with their theory. They must exclude all low grades of error as unimportant and physiologically normal—a point which experience in correcting small errors fully disproves. Small grades of ametropia are quite as often the cause of asthenopia as the larger ones; and while far from asserting that the weak glasses of my test case are the most important, I must needs recognize that this neglect of the low grades of refraction error is one of the few points in which Donders' great treatise has been found imperfect. One stronghold remains, but it is difficult to see how anything but blind prejudice can deem it impregnable. It is claimed by some that mydiatics give us a false view of the refractive condition of the eye, that paralysis of the accommodation is accompanied by a fictitious decrease of the refraction, and that the measurements so obtained must be "discounted" in order to arrive at the true *static refraction* or condition of entire rest. Merely negative evidence can be adduced in support of this view, and abundant positive evidence to the contrary is readily accessible. The oft-quoted statement of Donders is cited, that "a tone of accommodation" to the extent of .37 to .90 D. is usual and can be relaxed only by accommodative paralysis—a view from which he did not publicly recede, so far as I know. Yet he wrote to me as to this

in 1885: "The difference is slighter than I had supposed and may be neglected for the myopic eye. Another question is whether it depends on the tone of accommodation, which can only be supposed (as existing generally in not-striped muscular tissue), but not proved."

The resting points for this view are the facts that a mydriatic often shows a lower myopia or a higher hypermetropia than is discoverable before or after its use, and that most people complain of blurred distant vision if the full mydriatic correction is given.⁴ Most persons certainly do *at first*, or at least most hypermetropes; but it is exceedingly pertinent to ask why *all* do not, and why myopes are rarely much troubled in this regard. The answer is really self-evident—the myope has generally established no habitual accommodative tension; if it is present in any case, every one recognizes it as an "accommodative cramp," not a "tone." The hypermetrope, on the other hand, has so long maintained his accommodation tense, even in distant vision, that he finds it hard to unlearn the habit when it becomes no longer necessary. What ophthalmoscopist ever found it easy at once to relax all accommodative effort, or even after he has learned to relax, finds it always possible to do so? An eye whose accommodation has long been cramped is apt to return to its cramp when the mydriatic wears off, and will, therefore, see imperfectly at a distance with the totally correcting glass. If such a difficulty lasts more than a fortnight, as it will in a very few cases, it is almost invariably because of muscular insufficiency which has not been corrected. The essential question here to be considered is whether the mydriatic, pushed to total paralysis of the accommodation, invariably gives an untrue picture of the refraction and causes an artificial hypermetropia, as has been claimed. From two points of view this claim can be distinctly disproved. First, the cases are not very rare in which full mydriatic paralysis gives identically the same result as was obtained with active accommodation; and secondly, a large number of cases can be taught fully to relax their accommodation and obtain full vision with a glass totally correcting the defect revealed under the mydriatic. The length of time and the amount of annoying blurring before this is gained vary in different cases; and the question must always present itself to the practitioner, whether the benefits may not be fully gained and the discomfort lessened by giving an under-correcting glass. But this is a question of expediency, not of necessity; and those who habitually give total corrections and insist upon their constant wear, fail in few cases to obtain the desired result.

In the appended table of cases will be found, first, a group where the refraction was unchanged

⁴ As Dr. Jackson has pointed out, full correction for 5 metres is really 0.2 D. over-correction for distance, a point usually forgotten.

by the mydriatic; second, those who obtained full vision with totally correcting glasses; and third, a series to show how far astray the manifest error was from the true refraction. Of the first class of these cases, where the refraction was the same before and with the mydriatic, I have few accessible records, and I cannot, like Roosa, cite 6 eyes out of 20 which remained absolutely emmetropic under atropine. Yet every one who has put this matter to a fair test has met such cases, not only in middle life, but even in childhood. In the school examinations, Cohn reports 34 cases whose manifest hypermetropia was absolutely unchanged by total atropine mydriasis; and Dürr obtained like results under homatropine. Such cases, if not common, are not the less emphatic in their teaching. Of those who have received totally correcting glasses and with them have obtained full vision, dozens might be cited, although I have not tested and recorded the ultimate vision in even one-half of those who ceased to complain of blurring for distance, and have chosen only hypermetropes here as illustrations. Of the third group only a few are brought forward, because no one who has ever used a mydriatic can doubt that, in a large proportion of cases, the true result cannot possibly be obtained without it. These are all recent cases from my private record.

And here let me say as to my refraction work, that it is all done under conditions practically identical, with good uniform illumination on the test card, that the mistake of even a single letter in a long line has been signified by a question mark, that the minutest errors and discrepancies have been noted, and that full mydriatic paralysis has not been assumed merely because a mydriatic had been several times instilled, but proven by careful tests both for distance and for near. In the latter case an artificial far-point of 25 cm. has been generally used, and as the test object the finest of type or Burchardt's dots.

While a mydriatic has been habitually employed, it has been always regarded as a disagreeable measure, which should be avoided if possible; and accordingly, among the last 250 cases on my record, I find that there were 175 of refraction error (exclusive of presbyopia), and in 101 of these a mydriatic was used. Of the remainder, there were 53 patients less than 45 years of age to whom no mydriatic was given. This was not always from choice, for there were some of these cases where the mydriatic was advised, and the manifest glass was given only tentatively and under protest. There were also a few cases where I refused to give a glass without full use of a mydriatic, and thereby lost the patient: but these have not been included here. The method of employment has depended upon the mydriatic and the case. With hyoscyamiae sulphate, which I much prefer, a 2-gr. solution has been prescribed, to be instilled one drop in each eye at bedtime

and again on rising, with perhaps another instillation before the measurement. Dark coquilles or a thick veil have been worn to shade the eyes from glare, and the examination generally repeated, with continued instillation, on several days. Retinoscopy with the plane mirror at 4 metres distance, and the ophthalmoscope, have been used as control tests—the former being specially valuable, since with it discrepancies of .25 D. or of 5° in cylinder axis can hardly be overlooked.

As a mydriatic, hyoscyamine is probably unequalled. Chemically identical with duboisine, it yet seems distinctly less inclined to exert the toxic action which too often made the latter drug a treacherous ally; and in a strength of 2 grs. to the ounce it rarely causes any constitutional symptoms. Its action is more prompt and energetic than that of atropia in stronger solutions, and its full action is obtained in about half an hour. Even after a single instillation there is little or no diminution in its effect for about seventy hours, while the troublesome period of returning accommodation is only about two days. Recovery from its effect is as complete in five days as on the tenth day after the use of the atropia, although the grasp of the latter drug begins to waver much earlier, while the hyoscyamine is still in full control. A week can generally be set, therefore, as the time during which near work must be abandoned on its account, while the similar period for atropia is quite two weeks. This is a strong point in its favor, since it is quite trouble enough to disable the patient for the shorter period; but its highest value lies in the unvarying grasp upon the accommodation for about three days after the last instillation, so that the rest which it enforces is generally absolute. As this "putting the accommodation in splints" is one of the special indications for the use of a mydriatic, and one in which the atropia gives at most two days of rest, the superiority of the shorter-lived mydriatic is manifest. No value of this sort attaches to the use of homatropine; but in eyes that are not very irritable, total paralysis can be obtained by several instillations of a 6-gr. solution, and it has much value in its narrow field.

When, with or without a mydriatic, a glass is found which gives the best attainable vision and is confirmed by the retinoscopy and ophthalmoscope, there is room for judgment as to whether it shall be ordered as it stands or be modified to meet some special indication of the case; but there is in few cases anything but disadvantage in waiting until the mydriasis has wholly disappeared before ordering the glass. The accommodation and muscular condition should be determined at the first examination, and furnish, with the history, the only data which legitimately influence the decision as to the glass to be given. Upon one general rule I should like to insist, because

it would seem to be followed by few, and that is that the total correction should be given unmodified, except for clear and definite cause. It is not always wise to give full correction to myopes; but I am persuaded that if our European colleagues would do more of it, with careful correction of astigmatism, they would see far less progressive myopia. As has been said, it is sometimes very difficult to get a hypermetrope to accept the total mydriatic correction; and, in the absence of strabismus or asthenopia, policy may dictate a reduction of the convex spherical by .25 or .5 D. Insufficiency of convergence, especially for distance, generally makes the use of the total correcting glass impossible unless it is combined with a prismatic correction. This latter can often be most satisfactorily obtained by modification of the centring of the lenses. Inattention by oculists and opticians to this matter of precise centring is a prolific source of unsatisfactory results, which very little care could wholly avoid; and the oculist should specify the exact distance between the optical centres, and make a point of verifying the strength and fit of every glass he orders, if possible.

While there is little in the foregoing that can make the least claim to novelty, since most of it has been previously and better said, it contains much, I believe, which is at present accepted and applied in practice by only too small a minority. I beg leave, therefore, in closing, to reiterate the following points and to urge their importance upon all who are doing ophthalmological work:

1. Errors of refraction are present in the great majority of cases, but need correction in only a portion of those who suffer with eye-trouble.

2. In all correction of refraction errors, the manifest refraction is as uncertain a basis as a quicksand, and the *static* refraction is the only true basis on which to work.

3. A mydriatic is often required in order to give the eye a needed rest and to measure correctly the refraction, and it must be used to the extent of total ciliary paralysis to meet this end, as a small remnant of accommodation is sufficient to mask astigmatism as well as hypermetropia.

4. The glass as determined under full mydriatic paralysis measures the true static refraction of the eye.

5. The glass given should accord with the static refraction of the eye, being modified only for good and definite cause.

6. The minutest accuracy is desirable as to the strength and fitting of the glasses, and the width of the optical centres should be exactly prescribed.

7. The balance of the ocular muscles should be strictly studied in every case, since these relations have important bearings upon the ordering of lenses.

8. If these matters have been properly studied when the case is first seen, there is rarely any

need of delaying the ordering of the glasses until the accommodation has returned.

Cases illustrating refraction unchanged by full mydriasis:

1. Miss Kate S., aged 24; Right eye V. = $\frac{6}{8}$ +, no astigmatic lines chosen, near-point for D = .50 13 cm., with + .75 spherical V = $\frac{6}{8}$? +; under homatropine with + .90 or .75 sph. V = $\frac{6}{8}$: Left Eye V = $\frac{6}{8}$ +, with + .65 cylinder axis 180° V = $\frac{6}{8}$? +, under hom. with + .65 cyl. axis 180° $\frac{6}{8}$.

2. Miss Mary W., aged 24; R. E. $\frac{6}{8}$, with - 10. sph. $\frac{6}{8}$ +, no lines chosen; under hyoscyamine - 10. (with or without - .50 cyl. axis 15°) $\frac{6}{8}$? : L. E. $\frac{6}{8}$, - 10. sph. $\frac{6}{8}$ +; under the mydriatic - 10. s. \bigcirc - .50 cyl. axis 150° ? $\frac{6}{8}$? Without glass D = .50 5 to 10 cm. each.

3. George B., aged 16, R. E. $\frac{6}{8}$, no lines, D = .50 read from 8 to .25 cm., with - 3.25 sph. $\frac{6}{8}$; under homatropine with - 3.25 $\frac{6}{8}$: L. E. $\frac{6}{8}$, no lines, same accom., with - 4. sph. $\frac{6}{8}$; under hom., - 4. sph. (or - 3.5 s. \bigcirc - .50 c. axis 180° ? $\frac{6}{8}$).

Cases illustrating full vision through the totally correcting lens:

1. John W., aged 10; Right Eye V = $\frac{6}{8}$, lines chosen at 180° , near-point 11 cm. for D. .50, eye hypermetropic but vision made worse by any convex glass; under hyoscyamine with + 2.5 sph. \bigcirc + .90 cyl. axis 90° $\frac{6}{8}$. The left eye gave an identical result, before and after the mydriatic. Six months later he came with the glasses broken and claiming to see better without them; but saw $\frac{6}{8}$ and $\frac{6}{8}$ without, and $\frac{6}{8}$ each with them. A few months later his vision had risen to $\frac{6}{8}$? each through the glass, and accom. was normal.

2. Robert L., aged 17, R. E. $\frac{6}{8}$, lines at 180° , near-point 10 cm., with + 1. s. \bigcirc + .37 c. axis 90° $\frac{6}{8}$: L. E. same vision and accom., with + .90 s. \bigcirc + .37 c. axis 90° $\frac{6}{8}$ +. Hyoscyamine showed R. + 1.25 s. \bigcirc + .25 c. 90° $\frac{6}{8}$, and L. + 1.25 s. \bigcirc + .37 c. 90° $\frac{6}{8}$; and the result has remained unchanged since, although a low grade of exophoria is present.

3. Richard S., aged 33, R. E. $\frac{6}{8}$ $\frac{1}{2}$, lines 170° , near-point 22 cm., with - .50 cyl. 80° $\frac{6}{8}$; under hyosc. + .65 c. 180° gave $\frac{6}{8}$ $\frac{1}{2}$, which became later $\frac{6}{8}$? : L. E. $\frac{6}{8}$? +, with - .50 c. 100° $\frac{6}{8}$; under mydriatic + .25 s. \bigcirc .50 c. 150° gave $\frac{6}{8}$ $\frac{1}{2}$, later $\frac{6}{8}$.

4. Flora J., aged 13, R. E. $\frac{6}{8}$, no lines, near-point 11 cm., H. m. + .65 s. $\frac{6}{8}$; under hyosc. + .75 s. \bigcirc + .65 c. 90° gave $\frac{6}{8}$: L. E. $\frac{6}{8}$, no lines, D = 1.50 read at 17 cm., + 2. s. \bigcirc + 2.5 c. 90° $\frac{6}{8}$?; under hyosc. + 2. s. \bigcirc + 3. c. 90° gave $\frac{6}{8}$? +. A month later the vision was still $\frac{6}{8}$ + on the right and $\frac{6}{8}$? + on the left.

5. Sadie D., aged 26, R. E. $\frac{6}{8}$ $\frac{1}{2}$, lines 180° , near-point 15 cm., with + 2.5 s. \bigcirc + .64 c. 50° $\frac{6}{8}$?; under hyosc. + 3.25 s. \bigcirc + .50 c. 90° $\frac{6}{8}$? : L. E. $\frac{6}{8}$ $\frac{1}{2}$? , same lines and near point, with + 2.5

s. $\odot + .25$ c. $90^\circ \frac{6}{12}$?; under hyosc. $+ 3.25$ s. $\odot + .50$ c. $90^\circ \frac{6}{12}$. As this seemed a slight over-correction $+ 3$ s. $\odot + .50$ c. 90° was given, and with it three months later each eye saw $\frac{3}{4}$? Agnew had given sphericals $+ 2.75$ and 2.5 several years previously.

6. Miss M., aged 23, R. E. $\frac{6}{12}$?; no lines, near-point 22 cm., H. m. $+ .90$ s. $\frac{6}{12}$?; under hyosc. $+ 1.5$ s. $\odot + .37$ c. $90^\circ \frac{6}{12}$?; L. E. $\frac{6}{12}$?; no lines, same accom., with $+ .90$ s. $\frac{6}{12}$?; under the mydriatic with $+ 1.5$ s. $\odot + .37$ c. $90^\circ \frac{6}{12}$? $+$. She was still able to read many of $\frac{6}{8}$ with each eye when seen after the mydriatic had disappeared, and has remained comfortable with constant wear of her glass.

7. Mrs. L., aged 34, R. E. $\frac{6}{12}$?; no lines, H. m. $+ .25$, same vision; under hyosc. with $+ .25$ c. $90^\circ \frac{6}{12}$?; later $\frac{6}{8}$ full: L. E. $\frac{6}{12}$, lines 15° , with $+ 3.5$ c. axis $105^\circ \frac{6}{12}$?; under mydriatic $+ .5$ s. $\odot + 4.5$ c. axis $100^\circ \frac{6}{12}$?; same vision after return of accom.

8. Mrs. W., aged 44, R. E. $\frac{6}{12}$, lines 150° , with $+ 1$ s. $\odot + .50$ c. axis $60^\circ \frac{6}{12}$?; under hyosc. with $+ 1.5$ s. $\frac{6}{12}$?; later $\frac{6}{8}$: L. E. $\frac{6}{12}$, lines at 30° , with $+ 1.25$ s. $\odot + .50$ c. axis $120^\circ \frac{6}{12}$?; under hyosc. with $+ 1.75$ s. $\odot + .65$ c. axis $90^\circ \frac{6}{12}$?; later $\frac{6}{8}$?

9. Mrs. H., aged 30, R. E. $\frac{6}{12}$?; improved by no glass, lines 165° , read D = .5 at 15 cm.; under hyosc. with $+ .25$ s. $\odot + 1.5$ c. axis $90^\circ \frac{6}{12}$? $+$, later $\frac{6}{8}$?; L. E. $\frac{6}{12}$, lines 90° , D = .5 from 30 to 45 cm., with $+ 2$ s. $\frac{6}{12}$?; under hyosc. with $+ 3.5$ s. $\frac{6}{12}$, later $\frac{6}{8}$ $+$. The lowered vision was due to hazy and irregular corneae, worse on the right.

10. Mary C., aged 16, R. E. $\frac{6}{12}$, no lines, near-point 12 cm., with $+ .65$ s. $\frac{6}{12}$?; under hyosc. with $+ 1$ s. $\odot + .50$ c. axis $80^\circ \frac{6}{12}$?; L. E. $\frac{6}{12}$, no lines, same near-point, with $+ .90$ s. $\frac{6}{12}$?; under mydriatic with $+ .9$ s. $\odot + .65$ c. axis $100^\circ \frac{6}{12}$? $+$. As these seemed slightly over-correcting, $+ .75$ s. was given in combination with the cylinder for each eye; and when last seen the right had V = $\frac{6}{8}$, left $\frac{6}{8}$ full.

Cases illustrating marked differences between the manifest and true refraction.

1. Mrs. C., aged 38, R. E. $\frac{6}{12}$? $+$, lines chosen at 105° , near-point indeterminate, with $- 2$ c. axis $80^\circ \frac{6}{12}$? $+$; under hyosc. with $+ 2.25$ c. axis $120^\circ \frac{6}{12}$? $+$; L. E. $\frac{6}{12}$? $+$, lines at 105° , near-point 18 cm. for D = .5, with $- 2$ c. axis $165^\circ \frac{6}{12}$?; under hyosc. with $+ 2$ c. axis $80^\circ \frac{6}{12}$? $+$.

2. Lizzie K., aged 23, R. E. $\frac{6}{12}$, lines at 120° , large print spelled with difficulty, with $- 3$ s. $\odot - 2.5$ c. axis $35^\circ \frac{6}{12}$?; under hyoscine with $- 1$ s. $\odot - 4.5$ c. axis $45^\circ \frac{6}{12}$? $+$; L. E. $\frac{6}{12}$, lines at 60° , large print at 10 cm., with $- 4$ s. $\odot - 2.5$ c. axis $150^\circ \frac{6}{12}$?; under hyoscine with $- 1$ s. $\odot - 5$ c. axis $150^\circ \frac{6}{12}$? $+$. These seemed accurate, but the cylinders alone were ordered; and with them she had a month later $\frac{6}{12}$? each. Three

years later she returned with $\frac{6}{12}$, most of $\frac{6}{12}$, on the right and $\frac{6}{8}$ on the left, with these glasses. Her glasses had been frequently strengthened before coming to me, and she was wearing $- 6.5$ sphericals given by an optician "professor."

3. Miss M., aged 34, R. E. $\frac{6}{12}$? $+$, lines at 105° , large print at 35 cm., with $+ .65$ c. axis $105^\circ \frac{6}{12}$?; under hyosc. with $+ 3$ s. $\frac{6}{12}$?; L. E. $\frac{6}{12}$? $+$, no lines, near-point 25 cm., all glasses rejected; under hyosc. with $+ 2$ s. $\frac{6}{12}$? These were given, but worn little except for near work; with them when last seen $\frac{6}{12}$? right, and $\frac{6}{12}$? left.

4. Miss Minnie C., aged 22, R. E. $\frac{6}{12}$, with $- .75$ c. axis $105^\circ \frac{6}{12}$?; under homatr. with $+ 1$ s. $\odot + .50$ c. axis $20^\circ \frac{6}{12}$? $+$; L. E. $\frac{6}{12}$, with $- .25$ c. axis $75^\circ \frac{6}{12}$?; under hom. with $+ 1$ s. $\odot + .75$ c. axis $160^\circ \frac{6}{12}$ $+$. Some exophoria, and she had worn concave glasses.

5. Mrs. G. R., aged 22, R. E. $\frac{6}{12}$, lines at 75° , chose $- 3$ s. $\odot - 2$ c. axis 165° ?; under hyosc. with $- .75$ s. $\odot - 3.5$ c. axis $170^\circ \frac{6}{12}$?; L. E. $\frac{6}{12}$, lines at 100° , chose $- 1$ s. $\odot - 1.5$ c. axis 10° ?; under hyosc. with $- 2.75$ c. axis $10^\circ \frac{6}{12}$? With these the vision was slightly better when last seen.

DR. LIPPINCOTT: In the main I agree with the conclusions reached by Dr. Randall, because he distinctly states that the ametropia is to be fully corrected provided there is not some sufficient reason for not following this rule. In my opinion, cases presenting such conditions are not very unfrequently met with. For example: I sometimes find that the distortion of retinal images observed after correcting ametropia is so great that it becomes necessary to refrain from prescribing completely correcting glasses. This is especially noticeable in the case of artists affected with astigmatism of comparatively high degree and with axis oblique.

DR. JACKSON: The explanation of the period of complete rest of accommodation seems to me due to the excess of the dose used over the dose required to produce barely complete paralysis with the mydriatic used. I would confirm the reader's estimate of the benefit of giving the correcting lenses while the eyes are still under a mydriatic. A point not generally understood is that it is often as hard for the patient to become accustomed to partial correction as to a full correction, if the correction be for more than the manifest hyperopia. In some cases that have failed to see clearly with a partial correction of hyperopia, the full correction has been promptly accepted.

DR. DE SCHWEINITZ agreed entirely with the essayist, except in his choice of mydriatics, as he believed atropine was more efficient than hyosc. amine. In addition to the value of a strong mydriatic in aiding the determination of the refractive error accurately, this drug—atropine preferably, he thought—had a distinct therapeutic

tic influence upon the low-grade retino-choroidal irritations so commonly present in ametropic eyes—an influence, moreover, unattainable by a mere disuse of the eye without the local application of the drug.

THE PREVENTION OF MYOPIA.

Read at the Sixteenth Annual Meeting of the Mississippi Valley Medical Association at Louisville, Ky., Oct. 9, 1899.

BY FRANCIS DOWLING, M.D.,

OF CINCINNATI, O.

The simplest and at the same time the most concise definition of myopia is given by my friend and former teacher, Dr. Landolt, of Paris, when he says that "myopia is present whenever the retina is situated behind the focus of the dioptric system of the eye."

Before proceeding with the remarks on the means of preventing or limiting the development of myopia or near sight it will be well to give a brief outline of some of the principal causes of the affection, and for this purpose I have looked up the leading authorities on the subject. Schweigger, of the University of Berlin, is of the opinion that in the majority of cases myopia is congenital, or inherited, or, at least, there is a predisposition to it contracted through the parents. It occurs in early childhood and shows with the increase of years a progression both in frequency and degrees of development. Myopia may remain stationary through life, or at an advanced age it may show an apparent or actual decrease; the apparent decrease is due to the contraction of the pupil by which the circles of diffusion are made smaller and the images of distant objects more distinct. In other cases the affection is rapidly progressive during a period of life, generally up to about the twenty-fifth year, and after that remains stationary. Finally, in a small percentage of cases, the trouble is progressive through life.

Cases of myopia in children before the eighth year are extremely rare. On the other hand, previous to this age, hypermetropia generally exists. The trouble commences to manifest itself about the tenth year, and from that time on until the eighteenth year makes its greatest progress.

The accompanying table will serve to prove this fact. They are taken from the schools in the countries named:

GERMANY.		NEW YORK.		PARIS.	
Age.	Per cent.	Age.	Per cent.	Age.	Per cent.
6-8	11	6-8	3	7-9	6
9-10	15	9-10	5	9-13	6
10-11	20	11-12	10	11-13	6
13-14	25	15-16	15	10-19	8
15-16	40	17-18	20	10-15	13
16-17	45	18-19	25	13-15	4
17-18	50	20-21	26	13-16	23
18-19	55			15-18	25
19-20	60			15-19	50
20-21	62			17-19	75

It has been proven by statistics that myopia increases both in frequency and degree as one goes from the lower to the higher classes in schools. This might be explained by the fact that the age increases as one ascends in the classes, but statistics show that, irrespective of age, this increase in the frequency and degree of myopia bears a pretty regular ratio to the number of working hours. In this regard, Erismann, of St. Petersburg, gives the following statistics:

Among scholars occupied two hours per day, 17 per cent. myopia.

Among scholars occupied four hours per day, 29 per cent. Among scholars occupied six hours per day, 40 per cent. and so on.

Prof. Donders, of Utrecht, thinks that myopia is not equally prevalent in all countries, but is more particularly met with in cultivated nations, and further, that among the countries visited by him, he no where met with so many near-sighted people as in Germany. This tallies with my own experience: I witnessed proportionately more near-sighted people in the eye clinics of Germany than in any other country of Europe. Another thing I noticed was that the intellectual centres, or in other words, the university towns, had proportionately more near-sighted people than other places not university seats. Hence I infer that the very high educational standard in Germany, particularly in the college centres, by causing over-work of the eyes causes the greater percentage here than elsewhere.

Myopia is not usually directly transmitted from parents to children, but only a predisposition to the affection; in other words, all the conditions necessary to the production of the affection are inherited from the parents, needing only the addition of some exciting cause, such as over-exercise of the eyes in study, etc., to develop the affection in children, just as children of tuberculous parents inherit no consumption directly, but only the flat chest, the narrow shoulders, a weakly constitution, a tendency to contract colds, etc., in short, a predisposition to the disease.

It has been observed that in the transmission of this predisposition to myopia from the parents to the children, a father, as a general thing, transmits to sons only, and a mother to daughters. Cohn, in an analysis of some twenty-eight cases, found this rule to hold good. It is also found that in this hereditary transmission the affection usually confines itself to one sex; for instance, we often find that all the daughters in certain families are near-sighted, while the sons have normal vision.

In cases where both parents are myopic, the disease in being transmitted, manifests itself in a lighter degree in the children than in that of either parent, and very often it corresponds in degree to the sum of that found in both parents.

The time allotted for my paper is not sufficient

to enable me to enter into anything like an elaborate consideration of the causes of myopia, for this reason it will be sufficient to state here that the weight of testimony seems to show that the causation of myopia depends on two essential factors, the first of which is an inherent predisposition on the part of the person, inherited, or otherwise; the second a determining cause, which may be looked upon as a species of seed which when planted in the prepared soil of predisposition, causes the development of the disease.

Among the predisposing causes may be mentioned arrests of development of the sclerotic coat of the eye, a peculiar conformation of the globe, and chief of all, the disease called choroiditis in its various forms. In this connection it will be well to mention that in cases of hereditary predisposition there is a congenital weakness of the sclerotic coat, and more especially in its posterior half. The contents of the globe of the eye, under any undue exertion of the organ, causes pressure on this naturally weak spot; this pressure causes the membrane to stretch and give way in a measure, and thus are started many of the cases of so-called progressive myopia. Among determining causes may be mentioned the acts of convergence and accommodation in using the eyes for near work, as for example, in reading, writing, sewing, etc., as both these acts tend to increase the intraocular pressure of the eye, and the pressure, spending its force principally on the membranes of the eye causes them to stretch and give way, particularly in their posterior sections, and in this way the majority of cases of myopia are started, and if the cause is kept up, of course the trouble will continue to increase in degree.

The first endeavors to find out the causes of myopia, were, it seems, made in Germany, where the trouble prevails to a greater extent than in most other countries. In this country Dr. Cohn examined the eyes of some ten thousand children, and found that one thousand of them were more or less near-sighted. He also found that the trouble steadily increased, both in regard to the number of cases, and in the degree of refraction, as he went in his examination from the elementary to the higher schools. Another discovery which he made was that there were, relatively, more cases of myopia in badly lighted schools than in those that were more favorably arranged in this respect. The publication of these facts by Dr. Cohn caused quite a stir in the school boards of Europe. Lord Montague brought the matter before the British Parliament, and, although nothing definite was done by that august body, still the official notice of the facts in this way attracted to the matter the attention of educators at large, and whatever could be done to bring about a better state of affairs was done, and a better condition of school rooms, in

the way of illumination, fresh air, better printed books, a judicious abbreviation of the school hours, etc., were the results of the agitation. As a consequence there was a marked reduction of the percentage of myopia among the scholars in the schools where the reforms were carried out. In speaking of this subject, Florschütz says that the number of myopic pupils fell from 21 to 15 per cent. three years after the building of the Coburg schools, according to hygienic principles, and Von Hippel, in an address at the anniversary of the foundation of the University of Giesen, made the statement that he found only 34 per cent. of myopia in the new schools of Giesen compared with 49 per cent., which was the usual average in the old buildings.

Considering all the information that is at our disposal in regard to the factors that enter into the causation of myopia, both in its starting point and developing stage, no one ought to doubt that the prime factor in this causation is work with the eyes at near range; therefore, it stands to reason that the only way to prevent or restrict the affection is to limit or prevent altogether this near work with the eyes during the years that are known as progressive ones for the disease, viz.: from the tenth to the sixteenth year, and for this purpose I would make the following suggestions:

1. A child who shows any marked predisposition to myopia, and whose parents, one or both, were affected with the disease, should never be sent to the public schools, as they are now constituted, but should be sent rather to some private class where the number of hours of study and the tasks could be arranged to suit the condition of the scholar's eyes. Of course, the lighter the tasks and the fewer the hours, the better it will be for the eyes; this, in any given case, could be regulated by the family physician.

While on the subject it occurs to me that it would be a move in the line of progress, if a competent medical man could be appointed by our school authorities, particularly in our large cities, who should have general charge of the sanitary regulation of our public schools, and who should pay particular attention to regulating the tasks and the number of study hours for such of the pupils as showed any predisposition to myopia. To me it seems very unjust to have a uniform system of tasks and working hours for all pupils alike in the same grade, irrespective of the physical peculiarities of the individual scholars, for one who inherits a weakly constitution, weak eyes, etc., will necessarily deteriorate physically in trying to keep abreast of a colleague, who may be naturally endowed with stronger eyes, and stronger physical powers. Examples of this may be seen every day. If we look at the myopic scholars, for example, in our public schools, particularly in our own country where the rapid, high pressure system of education is in full vogue, and

where the standard is entirely too high, we find that a large percentage of these scholars are subjects with weary eyes, with pale, thin faces, in which the story is plainly written that the *mind* is being educated at the expense of the *body*.

2. The sanitary condition of the schools should be first-class, ventilation, light, etc., should be as near perfect as possible, and our school boards should spare no expense in keeping up this condition of things, for it has an immense influence both on the condition of the eyes as well as the general physical condition of the scholars.

3. Whenever the system of one affected with or predisposed to myopia, becomes at all relaxed, all work with the eyes should be suspended, until the health is again entirely restored to its normal condition: for it must be borne in mind, that it is during lowered conditions of the system that certain forms of myopia make their greatest progress.

In this connection it will be well to state, that from my own observations, especially in the clinics of Germany and France, a large percentage of those affected with myopia are burdened with some constitutional taint, such as the tuberculous, scrofulous, etc., owing to which, the powers of life are usually below a healthy standard, and this, in itself, is a potent factor in furthering the development of the myopia, and singularly enough, it is especially during the years that myopia makes its greatest progress, viz.: from the tenth to the twentieth year, that tuberculosis and its near relation, scrofula, make their greatest advances, therefore the condition of the general health of a young person predisposed to myopia should receive the most careful attention on the part of the medical adviser.

4. Young persons, who may be predisposed to myopia, should never study at night time, all near work with the eyes should be done by good clear sunlight. If, however, artificial light is used for this purpose, the electric light is the best of all its competitors, such as gas, oil, etc., being far less injurious to the eyes, for the reasons that in point of color it more nearly approaches that of the sun, than any other artificial light known: Then its volume is more uniformly distributed throughout the room, and by virtue of the great strength of its illuminating focus, it can be placed high above the head, and still be of uniform service; and lastly, the light does not vitiate the atmosphere of the room, like gas, oil, etc. If means could be invented to render the light steady, it would be the prince of all artificial lights for near work with the eyes.

5. The books from which one predisposed to myopia should study, ought to be printed with tolerably large type, and the Latin letters are the best of all others, as they are less fatiguing to the eyes than the German, etc. This fact is, probably, the reason why most scientific works and students' manuals throughout

the world are now printed in Latin letters, and one thing that surprises me is that Germany, with all her intellectual progress, still retains the old, crooked German letters in book printing, and particularly in the daily papers, which are the poorest printed of any in Europe, and the bulk of the population have to read this miserable print, by the equally miserable light of a candle, as gas light is only enjoyed by the few in Germany. This fact struck me as one of the causes of the great amount of myopia that is found, particularly among the middle and poorer classes of that country. But to return to our subject: in reading, writing, etc., the eyes should be kept at a distance of about 30 centimetres from the text, and the reading, etc., should be frequently interrupted, so as to rest the eyes, they should be closed for five minutes or so at a time, or directed at some far away point.

6. In cases where the myopia is at all marked, all work with the eyes, such as study, etc., should be postponed until the sixteenth year. The child should, if possible, be sent to live in the country, where the range of vision is longer than in the city, and then it should be kept outdoors, in the fresh air, as much as possible.

7. The wearing of glasses by a myope is optional, at least for distant vision, as they have very little, if any influence in checking the progress of the affection. They are only useful as a means of enabling the wearer to recognize more clearly his surroundings, and when worn should be of a weaker refractive power than that necessary to correct the actual degree of myopia present, and they should not, as a general thing, be put on before the fourteenth year.

If, however, the myopia is beyond a certain degree, say three dioptres, then the use of proper concave glasses for reading and all other near work, may limit in a measure the progress of the disease by relieving the strain on the muscles of convergence, and in this way lessening the tension on the globe of the eye, which is one of the great factors in furthering the march of the affection.

8. In tolerably pronounced degrees of myopia I have found paracentesis of the cornea by means of a fine needle to do a great deal of good. It relieves the intraocular pressure that is often very marked in such cases, and thus retards the progress of the myopia; then another thing, it lessens the chances of detachment of the retina, which often takes place in high degrees of the affection. In practicing the operation, after making the puncture in the cornea, I usually cause the fluid to escape from the anterior chamber slowly, by pressing on the cornea, alternately, with the lower and upper eyelid. Twice a week is as often as I practice this treatment in any given case. The great advantage in letting the fluid escape slowly, is that the shock to the eye is not as great as when it is emptied rapidly.

DR. HAROLD N. MOYER, of Chicago, in opening the discussion, said: While I do not claim to be competent to discuss this paper, yet I feel that something ought to be said because of its evident value. There is certainly no subject in the range of ophthalmology of greater practical importance than the one to which this paper has been addressed. It is an able contribution—one that should be widely read by the general profession. I trust that the writer will not have it printed in the *Archives of Ophthalmology* or in some equally specialized journal, but publish it in some widely circulated journal, so that it can be read by the whole profession; for it seems to me it will do a vast amount of good if it is put into the hands of the general practitioner. In this way the subject can be brought before the various school boards in small as well as large country towns, and indeed in every large city.

DR. C. H. HUGHES, of St. Louis, Mo.: Inasmuch as other gentlemen do not manifest a desire to discuss this interesting question, I can hardly permit such a paper to pass without expressing my appreciation, as a general observer in medicine and a practitioner of thirty-one years' active daily experience, of the value of the position taken by the author of the paper in regard to the best methods of preventing and ameliorating this condition among our school children.

Germany has become largely a nation of myopics, and I hope that will never be the fate of America. There is something in the organic aptitude of the individual that develops myopia. To illustrate: It is not necessary that either of the parents should be myopic, and this question comes as near home to me as any one in medicine, for, belonging to a family that never had to wear glasses prematurely; married to a lady none of whose family had to wear glasses prematurely, there has developed in my family (in one of my children) this trouble. All of the other members of the family are free from it. I never wore a glass of any kind, nor my father or mother, until from 43 to 45 years of age, and these are the circumstances under which myopia appeared in my child.

At the age of 6 years the child became the victim of an exhausting fever—scarlatina. He convalesced tardily so far as the restoration of general vigor was concerned. There were no aural sequelæ, but there was evidence of damage done to the central (neural ganglionic) influences which preside over the nutritional processes of the organism, and it was with the utmost difficulty that I succeeded in rescuing my boy from decline. It became necessary to resort to all the therapeutic resources which would occur to a solicitous father practically familiar with the resources of our art. He was carefully and thoroughly nourished, he was tranquilized at night,

so that he did not lose the sleep he required for recuperation, his digestion was taken care of, and I traveled with him into invigorating atmospheres, but, in spite of all care, myopia developed. It is the first case that has shown itself in my family. There is no ancestral history which would lead us to expect it to appear in the family.

There is a great deal more behind myopia than is dreamed of in our present philosophy. We are very apt to explain it by attributing it to congenital deficiency of development alone, though it undoubtedly is the direct and immediate causative factor. But what is it in the organism of the child that singles out one of a family and, in the process of evolution from infancy up through childhood, causes the appearance of this deficiency? Of course, it is a failure in the central nutritional processes. There is a *minus* condition there instead of that *plus* process. There is a neuratrophic predisposition which makes the sequent myopia a possibility in myopics, and this may be either congenital or acquired. Myopic eyes are like congenitally shortened limbs, or like those trophic lesions that follow certain nerve trunk or nerve injuries, only in lessened degree. The methods of treatment, to be successful, must extend beyond the eye, and the oculist who satisfies himself with the immediate rectification of the condition of the eye alone that presents itself, will have only final failure for his pains.

Now, since the doctor advises outdoor exercise and all the conditions necessary for the proper evolutionary and developmental processes going on in the child, I would like to have him observe in the practice of his cases in the future the result of that treatment, and to find out how many of them are arrested and what proportion are ever cured. It is a question that becomes interesting when it strikes one's own family, and there is no doubt in my mind that myopia is just as much a product of abnormal and inadequate nutritional processes in the organism as the defective conditions in neurotics are, and the ophthalmologist, like the neurologist, otologist, or any other man who does special work in medicine, is the most successful practitioner who extends his range of observation and treatment beyond his immediate environment or practical work.

DR. C. W. MCINTYRE, of New Albany, Ind.: I do not know whether or not the writer of the paper called attention to the fact, that one of the principal causes of myopia is absence of proper light in residences as well as in school houses, but I know that to be true from experience. Myopic patients come to my office and consult me, and, after inquiry, they inform me that their residences and workshops are not properly lighted as I think they should be, and it is really necessary for our school boards to look after the sanitary condition of the schools in so far as they are properly lighted, etc.

THE CLINIC.

UTERINE MYOMA—RENAL CALCULUS
AND SURGICAL OPERATIONS UPON
THE KIDNEY.

*A Clinical Lecture Delivered at the Regular Surgical Clinic at
Rush Medical College, Chicago, Thursday, Oct. 2, 1890.*

BY CHARLES T. PARKES, M.D.,
PROFESSOR OF SURGERY.

I differ with the essayist in one particular, and that is, that the electric light is preferable to the other lights which he mentioned. I think an extreme light is just as damaging to the eye as insufficient light. We know that a number of myopic patients trace their condition to improper glasses used in reading or working. If our sanitary officers were to look after this, we would have less myopia in this country. If there is not more done in the future than there has been in the past, I fear we will get into a condition like Germany. It is necessary for every physician to take this matter into consideration.

As Dr. Moyer said, the paper should be placed in the hands of not only every specialist who devotes himself to ophthalmology, but it should reach the eye of every local practitioner, because we all have more or less of this class of patients which require our attention.

I wish to emphasize the fact that the absence of proper and sufficient light in residences and school houses is one of the principal causes of myopia as well as amblyopia.

DR. DOWLING, in closing the discussion, said: Something should be done to prevent this growing trouble. I am satisfied that were it not for intermarriages, especially in university centres, it would only be a question of time when we would all become myopics in this country. Were it not for the fact that people from the country intermarry with those of the city, myopia would be more prevalent than it is. This intermarriage is the only thing that saves us from becoming myopics. It occurs to me that it is becoming more and more frequent, especially in children, in our large cities. Take, for instance, Cincinnati, or any other large city, and we will meet with a large number of cases.

I believe that the appointment of a private medical officer would be a step in the right direction. I spoke to my friend, Dr. Culbertson, not long ago about this, and he said the health officer was supposed to attend to it. The average health officer has no time to attend to such matters. In a large city with perhaps twenty-five or more school districts, it would take up a good deal of time; nevertheless I maintain that a medical practitioner should be appointed to look after the sanitary condition of the students and regulate their hours of study, etc.

In order that the changes produced in tuberculous tissues by Koch's fluid may be determined as accurately as possible, the directors of the Charité Hospital at Berlin have given orders that the bodies of any patients who may die after having been treated by the new method shall be examined as soon after death as the law permits. Koch found such early examinations a great help in his investigations on cholera.

Gentlemen:—The patient before you, Mrs. J. F., æt. 37, is suffering from an abdominal tumor which has been present a number of years, all the time gradually, and of late, rapidly increasing in size, until it has reached the large growth which you see fills the entire abdomen now that it is displayed to view. It is a source of serious trouble and annoyance to her and the burden of it is surely undermining her general health.

She has faithfully, during the last five years, tried various remedies and treatments, but they have proved of no avail; so under our advice, she has come to obtain relief by the removal of the mass.

Quite a variety of opinions have been expressed by different physicians whom she has consulted, as to the nature of the tumor; and this diversity of opinions increases the item of doubt which surrounds all extensive growths concealed by the abdominal walls.

Some have decided that it is an ovarian tumor, cystic in character; others have supposed it to be an outgrowth from the uterus itself, forming what is called a fibroid tumor or myoma. The difference between these two varieties of tumor is very wide indeed, and usually there is no difficulty attending the diagnosis between them.

It makes, also, a very great difference to the patient whether the tumor is connected with the ovary solely or with the uterus. If connected with the ovary it is usually easily and safely removable; if an outgrowth of the uterus, it is removed many times with great difficulty, and the removal is dangerous to the patient, for, in the majority of cases, the uterus and its appendages must be removed with the tumor.

Now we will go over the salient points in the diagnosis of this tumor.

1. It has been slow of growth, giving a history of several years' duration, commencing low down in the midline of the abdomen where it was first discovered as a small hard mass. Its growth has been unattended, until within the last year, with any serious interference in any way with the patient's general health. Its growth for the first year was accompanied with a very noticeable increase in the amount of blood lost at each menstrual period, but the amount of blood lost has never been extremely severe.

2. Palpation of the abdomen shows that the

tumor is considerably larger than the uterus at full term; that it is smooth, even and regular all over the surface; that it is very hard and resistant to the touch; that it is non-elastic and does not fluctuate as a whole or in circumscribed areas. It is freely movable as a mass from side to side within small boundaries.

3. Percussion gives an absolutely flat sound all over the surface, with a boundary of resonance above it and in the post-lumbar regions.

4. Vaginal examination determines that the cervix is of normal size and length, and in proper position, rather high, as if lifted up. The finger, by pushing the vaginal walls upward, shows the cervix to seemingly grow upwards into a dense mass which cannot be limited. With the finger on the cervix, any and every motion made in the tumor by pressure through the abdominal walls is immediately transmitted to the cervix and it is moved accordingly.

All of these signs together lead me to the conclusion that we have to deal with a uterine tumor or myoma. The patient has been so informed, and she has been made thoroughly acquainted with the dangers attending the removal of tumors of this variety.

Well aware of the uncertainty in diagnosis accompanying all abdominal growths of large size, there will be some anxiety attending the disclosures of the abdominal incision. As soon as this is made the diagnosis can be definitely settled. The tumor's removal can only be accomplished by this incision which will now be made.

The opening through the abdominal walls should be made in the line of the linea alba from just below the umbilicus toward the pubis by a free use of the knife, and without a director, until the transversalis fascia is reached, as has just been done. Its length at first should be at least three inches, subsequently prolonged to reach the requirements of every special case.

When this deep fascia is uncovered to the full length of the opening through the skin, you should stop long enough to control the bleeding points in the wound. This is done temporarily by the application of these forceps; usually before the operation is completed, their pressure has permanently controlled the bleeding. This also prevents the blood from entering the peritoneal cavity when it is opened.

The opening through the remaining tissues, the transversalis fascia and the peritoneum, should be made carefully, in order to avoid wounding the bladder which is very likely to be carried up from its normal position into the line of the incision, in the development of a uterine tumor. It will also avoid wounding the tumor itself, or any other important viscus which may lie on the anterior surface of the tumor or between it and the abdominal wall.

This is best accomplished in all cases, by the plan usual with us, which we will now illustrate.

With these dissecting forceps the tissues at the extreme upper end of the abdominal incision, are seized by the operator and raised; at the same time the assistant, with similar forceps, raises them on the opposite side. With a free stroke of the knife an incision is made between the forceps. This procedure is repeated until a small opening is made into the peritoneum.

As soon as this is accomplished, one is frequently made aware of it, by the flow of peritoneal fluid through the opening, and a sight of the tumor. By this method the opening through the peritoneum is least likely to endanger the bladder.

The opening is very small, the tumor can just be seen through it, and yet I am satisfied that the diagnosis of myoma is the correct one, principally on account of the color of the tumor, which is dark red and vascular looking. Cystic tumors are steel white and shining.

With the finger inside the cavity, as a guide, the peritoneum is divided to the full length of the external incision. Now it is possible to see and feel the entire tumor and its relations. It has no adhesions—the bladder is not attached to its anterior surface. The broad ligaments are elongated and carried up to the highest point of the tumor on either side. One can see the immensely enlarged veins coursing between their layers. Here are the enlarged and elongated Fallopian tubes and the ovaries carried from their normal position high up into the abdominal cavity.

There can now be no doubt as to the character of the tumor. It cannot be drawn out through this small incision, so this must be enlarged upwards beyond the umbilicus sufficiently before the tumor can be delivered through the wound.

Before doing this it is best to introduce into the abdomen this large, thin, flat sponge, and to spread it out smoothly over the intestines, between them and the abdominal walls, in order to protect them and to keep them from bulging into the wound as it is increased in length.

This has been done and the incision made, controlling the bleeding as at first. A pair of snap forceps is put upon the peritoneal edge here and there to keep it from retracting or being pushed off the muscles of the abdomen. You notice that the sponge protects the intestines perfectly and enables the assistant to keep them up in the cavity of the abdomen, well out of the way of operative manipulation, in a manner entirely isolating the pelvis—this is a very necessary procedure.

As yet it is impossible for me to lift the tumor out of the pelvis so as to get at the proper point for its division. So that the next procedure consists in securing and dividing the broad liga-

ments on either side, for they bind the tumor down into the pelvis. This is called technically "tying off" the broad ligaments and requires great care, in order to avoid opening any of the large veins and to enable one to apply ligatures to the ligament for the permanent closure of all the vessels included in its folds.

It is done by seizing the broad ligament as close as possible to the uterus with the thumb and finger of the left hand at a point about half way down its lateral wall, and pulling the included tissues away from the uterine wall. With the right hand a pair of blunt pointed forceps are thrust through the ligament between the fingers and the uterus and opened laterally, in this way a separation is made close to the uterus without opening any large vessels.

Through this opening a needle armed with a long double thread is passed. As soon as it is drawn well through, a sufficient length of it is cut off to answer the purpose of tying that portion of the ligament which is left attached to the tumor and towards its top. This ligature is tied as close to the top of the tumor as it can be drawn, and prevents bleeding from the uterine side of the broad ligament.

The needle is still threaded and lies inside of the outer portion of the ligament. The thread is drawn through the needle far enough to make a second double ligature. The needle is then carried through the remaining outer portion of the broad ligament, at a non-vascular point, and this portion is tied in halves, just as one would tie the pedicle of an ovarian tumor. In this way all the vessels are securely fastened, and as the stump of the broad ligament is bisected by the ligature, it is very secure and little likely to slip.

This procedure is repeated in securing the broad ligament on the other side, and now the mass can be lifted out of the pelvis and we are ready to proceed to the next step of the operation, which is to permanently close the vessels in the uterus and tumor previous to its separation. This is done by tying around the lower part of the tumor this piece of rubber tubing. The rubber tube is as large as the middle finger, and when in position, should be drawn as tight as your strength will permit, its ends crossed once and secured temporarily at the point of crossing by a Nelaton forcep.

The determination to practice the intra- or extra-abdominal method of treating the stump was made before the operation was begun. In this case we will adopt the extra-abdominal method because it has given the largest number of recoveries. The tube is applied at such height on the tumor, so that when the abdomen is closed, the rubber tube will be outside of the abdominal cavity without any tension on the stump. It is now in position and fastened so that we can divide the uterus and remove the tumor.

It is very essential to ascertain the position of the bladder before the rubber tube is fastened, in order to avoid including this viscus in its grasp. If the bladder is drawn upwards on to the anterior surface of the tumor, it must be carefully dissected away from the tumor before the rubber is applied.

In cutting away the tumor, the incision should be made sufficiently far away from the rubber to leave tissue enough outside of it to prevent the rubber from slipping over the end of the stump. It is proper to introduce a strong pin through the substance of the stump outside of the rubber cord, to further guard against the occurrence of any such accident.

Cases in which the tumor develops low down and implicates the cervix to such an extent as to prevent apparently the formation of a pedicle, can be managed safely in the following manner:

1. Apply the rubber cord as low down as possible, near to the vaginal juncture, to control hæmorrhage temporarily.

2. Remove the tumor by an incision through its substance, without reference to its size, high enough to make the pedicle sufficiently long.

3. Enucleate from the stump all the separate myomata, if there be any, or the pieces of myomatous tissue that may be found in it.

4. Apply the permanent ligature at the proper height and remove the temporary ligature.

Cases of myoma are not infrequently met with in which a true myomotomy can be done. In these cases the tumor is moderate in size, grows in the anterior or posterior wall of the uterus.

It is uncovered by an incision through the thin layer of uterine tissue investing it, when it can be shelled out or enucleated by the finger with ease, without opening the uterine cavity. The walls of the cavity thus left are brought together securely by a series of interrupted catgut sutures, commencing at the bottom; and the peritoneal edges are united by a continuous catgut suture. In such cases neither the uterus nor its appendages are disturbed.

Hæmorrhage is controlled temporarily by the rubber cord drawn over the uterus and broad ligaments below the tumor. The cord is removed as soon as the wound is thoroughly sutured.

Now that the tumor is removed we see that the uterine cavity is opened. We proceed at once to disinfect this cavity by the use of the actual canterly or pure carbolic acid in order to avoid infection from this source. After this is done the stump is entirely shut off from the abdominal cavity by sewing the peritoneal covering of the stump to the peritoneum of the abdominal walls, at the lower end of the wound. This is accomplished by a continuous catgut suture encircling the entire circumference of the stump, closely approximating these peritoneal surfaces.

Adhesions soon form and entirely occlude the abdominal opening at this point, preventing subsequent infection.

The peritoneal cavity is carefully cleaned of all blood clots, and if the large flat sponges have been properly placed, there is very little manipulation required for this purpose; as they have kept every thing out of the cavity.

Now make a careful survey of the entire field of operation to see that all the vessels are secure, also have all the sponges counted. You should know absolutely how many there should be, and it is well to get into the habit of using the same number for every abdominal operation.

The rubber tube is now permanently fastened, previously removing the Nelaton forceps, by a silk thread carried through the tube at the point at which the ends are crossed, and securely tied.

Next the abdominal wound is closed by a series of interrupted silk stitches passed through all the tissues of the abdominal walls at intervals of about half an inch. It is well to have the last stitch above, and the first below the stump, include some of the stump tissue, thus making sure the isolation of the stump from the cavity.

Last of all the dressing: The free surface of the stump is mummified by a large quantity of iodoform powder, or by the use of the actual cautery. In this case we use the iodoform. A narrow piece of iodoform gauze is placed around and beneath the projecting borders of the stump; the abdominal wound and the entire abdominal walls are covered with a free dressing of iodoform, iodoform gauze, and cotton batting, retained in position by a broad abdominal bandage.

The operation is now complete and the patient is in good condition, showing no signs of shock or exhaustion. The perils the patient has to encounter are first, from hæmorrhage caused by some fault in controlling the vessels; and second, from septic peritonitis. There is little fear from the former on account of the care we have taken. From the latter source the danger is greater, for in extensive operations of this kind the danger from infection is extreme, and cannot always be avoided even when practicing the most vigilant care to prevent it. If we have not infected the patient she will recover from the operation with little trouble.

The specimen is a beautiful example of uterine myoma. It shows how these tumors are often multiple, and how easily the separate masses can be enucleated out of their bed or capsule of condensed connective tissue. You will have an opportunity to examine it; you will be impressed with its density and hardness, so that in the future this sign of its character can be easily recognized by you.

The patient will be put into an even, smooth, well warmed single bed, with bottles of hot water about her under the cover.

In order to relax the abdomen and remove all possible tension from the recent and tender wound, a pillow should be placed under the bended knees, and her shoulders slightly elevated.

The bladder should be emptied every six or eight hours, by means of a thoroughly aseptic catheter, unless the patient herself can empty it without discomfort.

If the anæsthetic causes nausea, this will be best controlled by keeping the stomach absolutely empty, still occasionally this distressing condition is relieved by teaspoonful doses of very hot water.

Thirst and dryness of the tongue and mouth, is in part controlled by wetting the lips and mouth frequently with cold water. If all goes well, these symptoms will pass away inside of forty-eight hours, during which time the patient must be encouraged by cheerful attention. No feeding should be attempted until they have subsided, after which the patient can be fed any kind of bland nourishment, gradually increasing its strength to normal diet.

It is a good plan to secure an evacuation of the bowels at least on the third or fourth day, or sooner, if the nausea persists and there is some tympanitis present. This can be accomplished by administering teaspoonful doses of sulphate of magnesia or Tarrant's aperient, at intervals of three hours, until four doses are given, unless the desired effect is produced sooner. This result may be assisted by glycerine enemata.

If the patient has much pain, my partiality is the use of an injection containing thirty drops of deod. tinct. of opium, one drachm of whisky and two ounces of beef tea. Repeated if required by the severity of the distress.

The external wound will need no attention if there be absence of rise of temperature, until the seventh day, when, if union is complete, the stitches may be removed and new dressings applied.

Just as much care must be used to prevent infection during the dressing as during the operation. The stump will probably be separated entirely by the third week, when it can be removed and the remaining excavated ulcer dressed with ordinary care, until it is filled up with granulations and cicatrized over.

After as severe an operation as this, the patient should be kept in the recumbent or semi-recumbent position, for at least four weeks.

RENAL CALCULUS AND SURGICAL OPERATIONS UPON THE KIDNEY.

The next patient has this history: Three years ago she was taken with severe pain, suddenly coming on, referred to the left side of the abdomen in the neighborhood of the left kidney. The pain extended over the front of the abdomen, after a time, and spasms of it, described as shoot-

ing, ran down towards the left side of the pubis. After lasting for a few hours it ceased quite as suddenly as it began.

During the presence of the pain the patient felt a frequent desire to pass urine, but discharged only a tablespoonful or so at every attempt to evacuate the bladder, and its passage was accompanied with considerable tenesmus and a severe burning pain. When the attack ended the urination was accomplished easily and attended with a large flow of urine.

In addition to the agonizing pain which marked the onset of this attack, and which persisted during its continuance, the patient suffered from nausea and vomiting. There was also great pallor of countenance; the features were pinched; the skin was bathed in clammy perspiration; and all these were associated with symptoms of profound constitutional disturbance of the circulation and nervous system.

This aggregation of symptoms accompany the passage of a renal calculus, or kidney stone, from the pelvis of the kidney into the ureter or through it into the bladder.

The pain commences as soon as the stone enters the ureter, and does not cease until it either falls back into the pelvis of the kidney or is forced by the accumulation of urine behind, aided by the contractions of the muscular fibers of the ureter, through the length of this tube into the bladder. Knowing this you can readily understand the special character of the accompanying pain, in that it commences suddenly and ends as quickly. This cycle of events is termed technically an attack of renal colic.

Remembering that there is a fair sized cavity at the renal end of the ureter, consisting of the pelvis of the kidney, and a very large cavity at the opposite end, in the shape of the bladder, you are prepared to understand how a stone or a shred of tubercular tissue, or a dense clot of blood, may, on the other hand, just enter the ureter and be displaced therefrom by some sudden movement of the patient. The renal colic caused by its impingement in the ureter suddenly ceases when it falls back into the pelvis.

As well can you understand how the attack of colic is far more severe and more prolonged if either of the foreign bodies mentioned is compelled to make the long transit through the entire ureter into the bladder, when the pain will also cease suddenly.

Such like attacks of colic will occur at intervals so long as calculi form in the calices of the kidney, and are displaced therefrom, and take up their journey to the bladder, as is the condition in quite a number of individuals.

Similar attacks may occur if there is present in any patient certain other pathological conditions of the kidney, such as tuberculosis, or cancer, or papilloma, etc. It is true also that calculous

formations are very apt to be associated with these pathological conditions.

We find in this patient, that she was free from any return of the attack until eighteen months after the first manifestation described, since then she has suffered from them as often as once in every two or three months. Since the second attack, the urine has contained gravelly concretions of urinary salts, some of them of considerable size, as large as a kernel of wheat, or larger. The urine has shown the presence of pus and blood in some quantity; of late the pus has been present in large quantities.

The patient's general health has suffered very much, until now she is emaciated, weak and broken down in spirits and physical strength, and is practically a confirmed invalid.

Some time ago her attending physician, while making an examination of the painful region during an attack of colic, discovered a tumor occupying the situation of the left kidney, and now you can see this tumor, showing as a slight projection of the abdominal walls on the left side over the neighborhood of the kidney. It is quite easy to feel it with the fingers of one hand pressed against the tissues between the last rib and the crest of the ilium, while the other hand is pressed against the front of the abdominal walls.

It is slightly movable, semi-elastic, smooth and even of surface, and is the left kidney distended with fluid of some kind. Probably the fluid is pus, as such a large quantity of this material is found in the urine, and its presence is due to infection with the pus microbe through the genito-urinary tract.

It is my belief also, that there is present one or more calculi, and this is based upon the fact that so many calculous concretions have been passed in the urine, as well as upon the fact that renal calculi are very sure, sooner or later, to be accompanied by an accumulation of pus through infection.

It is scarcely possible that this will prove to be a kidney affected with tuberculosis either with or without a stone, because it is unusual to have no other manifestations of the tubercular infection than is present in this one kidney, besides the bacillus of tuberculosis has not been found.

The diagnosis in this case is renal calculus with suppurating kidney.

It is, as well, certain to me that the substance and capsule of the kidney is intact, because had destruction of these taken place by ulceration or tissue necrosis, a peri-nephritic abscess would have formed, with the usual signs of accumulation in and bulging of this space between the rib and ilium.

A few days ago, we had occasion to direct you that whenever a patient came under your charge suffering from indications of bladder disease, never to think your examination is complete until a sound has carefully searched every portion of the blad-

der cavity. In this case we have an additional caution to give: never to be satisfied with an examination of a case of disease of the genito-urinary apparatus, without a rigorous inquiry into the condition of the kidneys, by resorting to inspection and palpation of the organs themselves, as well as their entire neighborhood, just as carefully as you would examine their secretions microscopically, and by all known tests, for evidence of change from normal condition.

In all these operations the primary incision to expose the kidney is made in exactly the same way, and all the steps will be illustrated to you upon this patient; and as we will no doubt find a calculus and remove it—this will be a nephro-lithotomy.

The direction is given, in order to make the diagnosis in such cases absolute, to sound the kidney by means of an exploring needle carried into the substance of the kidney, with the hope of having it come in contact with the stone—to strike the stone as it is termed—a very positive confirmation, if it can be elicited. It is even advised to go so far as to introduce the needle into the organ in several different directions for this purpose; and the trial has often been made before the primary incision uncovers the kidney, but of course oftener with failure than with success attending its practice.

Even after the kidney is to be seen at the bottom of the external wound, the exploring needle, or the probe, or even the finger introduced into the pelvis of the kidney or through its substance, sometimes fails to find the calculus; especially when it is small and hidden in an expanded calyx. Consequently you are not to conclude hastily that there is no stone present if this test fails even when the kidney itself is under inspection; certainly not, if the trial does not determine its presence when the instrument is introduced without an incision.

Given pointed and unmistakable evidence of the foreign body, as indicated by the occurrence of repeated attacks of renal colic,—with deep-seated and continuous pain referred to one kidney,—with pus or blood or both, in the urine, even in comparatively small quantities, yet constantly discoverable; with the history of the passage of concretions of urinary salts; certainly if several, or all of these signs are present in a marked degree, the surgeon is justified in exposing the kidney and incising its walls freely, in order that the pelvis can be explored in all directions and portions, by the finger—truly the only reliable probe.

It is true that even this crucial procedure sometimes fails to bring forth the calculus or to discover its presence. The kidney has been exposed a number of times and the pelvis explored without finding a stone. The renowned Mr. Henry Morris, of England, relates a case in which failure followed his search, but, so well convinced was he of the presence of the foreign

body, on account of the marked symptoms of his patient, that he proceeded to do a nephrectomy and found the stone in one of the calices of the kidney after the organ had been removed from the body. Mr. Morris was among the first, if not the first, to diagnose the presence of a stone in the human kidney and to deliberately plan, and successfully execute, an operation for its removal.

It has happened to me to fail to find a calculus on two occasions. In one a large calculus had been removed from the other kidney a year previously; in the other it seemed certain that the stone was lodged low down in the ureter. We may be able to get at it yet.

If an operation is done merely to expose the kidney and incise it, the operation is termed a nephrotomy. If, in addition, the operation is done to remove a calculus from the kidney, it is termed nephro-lithotomy. If the operation is to relieve the distressing symptoms due to the extreme mobility of the organ, called a movable kidney, in which the organ is first exposed and then fastened in some way to the edges of the wound, it is termed a nephrorraphy. If the operation is done to remove the entire kidney through the tissues of the back, it is termed lumbar nephrectomy.

Prognosis.—The successful ending of the many operations already done and being done upon the kidney for a variety of diseases, is leading surgeons to the conclusion that the operations are not especially hazardous. My own experience, embracing all the operations performed upon this organ, and including several repetitions of some of them, points in the same direction. There has been but one death, and that followed the most formidable of them—a nephrectomy for a greatly enlarged suppurating kidney. All of the operations short of nephrectomy have ended favorably and with rapid recovery. The simpler procedures of exposing and exploring the organ are not attended with much danger, if such rigorous aseptic precautions are taken as are recognized by every surgeon as necessary in all operations.

You understand that the incisions which we will make in this case, are exactly the same in every respect as those which are necessary for the execution of a nephrotomy, a nephrorraphy or a nephrectomy. The external incision should be about four inches in length, and made parallel with the last rib and fully half an inch below its lower border; commencing posteriorly, a little behind the prominent ridge marking the external border of the erector-spinae muscle. The course of the incision should always be made as directed, at the distance mentioned below the border of the last rib, on account of the dangers of opening the pleural cavity in any case in which the pleura descends below that rib or in such cases as there is present a supernumerary rib, or in which one rib is absent, and the normal relations of the pleura thereby altered.

The patient should be placed in the position here illustrated, on the sound side, with a tightly-rolled pillow, covered with an oil-cloth having an aseptic towel over it, placed under the opposite loin; thus the side to be operated upon will be made very prominent, and the interval between the rib and the crest of the ilium increased to its fullest extent.

The first incision should be carried with a free hand through all the tissues and fasciæ down to the anterior layer lumbar fascia. The length of the incision through the deep tissues being the same as that through the skin. The operator should avoid opening the sheath of the erector-spinae muscle. All bleeding vessels are secured.

The anterior layer of the lumbar fascia is then opened and divided to the extent of the wound. As soon as this is done, there will bulge into this opening, the peri-nephritic tissue in which the kidney rests. Its investing connective tissue should be opened and the operator will then readily recognize the peculiar white fat surrounding this organ. A portion of this fat may be pulled out and snipped away, or its spaces opened and torn by the fingers, as you now see me do, after which the kidney can be readily felt by the finger or seen with the eye, as a darkish red body, moving slowly up and down with each respiratory act.

If the kidney is not now easily found, as is frequently the case if it is not enlarged to any extent, it can be brought into view sometimes by a simple procedure. An assistant introduces two fingers into the wound and pulls strongly upward against the last rib. This widens the wound and at the same time stretches the peri nephritic tissues towards the wound. The assistant with his disengaged hand should also press strongly backwards through the anterior abdominal walls over the region of the kidney, thus pushing it into the wound.

The space for operative manipulations, in cases of enlarged kidney, can be greatly increased, and with safety, by a vertical incision commencing in the one already made, and carried downwards towards, and forward parallel with, and close to the crest of the ilium. With the finger deep in the wound as a guide, this latter incision can be rapidly made without danger of opening the peritonæum.

It was used upon one occasion successfully by myself in the removal of a kidney enlarged to the size of a coconut; and made a space large enough for all the necessary manipulations without difficulty.

After the kidney is exposed in the manner described and brought fairly under the touch of the finger and the sight of the eye, by the removal of its investing fat, the next step will depend upon the operation which is being performed.

In this case the object is to remove a stone from

the kidney and evacuate what other accumulations may be present. So we will now first introduce the finger into the wound and palpate the kidney over its anterior and posterior surfaces, reaching as far beyond the pelvis as possible in both directions.

The best command of the kidney can be obtained in these cases, by the finger passed over its posterior surface. The finger used in this way will sometimes detect the stone in the kidney, or determine a noticeable bulging and hardness in some portion of its surface which may indicate its presence.

(To be concluded.)

MEDICAL PROGRESS.

Therapeutics and Pharmacology.

REMARKS ON LAPAROTOMY FOR PERITONEAL TUBERCULOSIS. — LAUENSTEIN (*Centralblatt für Chirurgie*) thinks that it is remarkable that the usefulness of this operation should have been accidentally discovered, and that it should have been practiced empirically to the extent which it has. He would refer the good effects to two facts in the life history of the bacillus: it requires moisture, and is rapidly killed, even by a few minutes' exposure to the direct rays of the sun. He thinks that both of these factors may explain some of the good effects. In operating he allows the direct rays of the sun to fall upon the abdomen and its contents. Of course, the operation relieves the ascites always present in these cases, and so lessens the amount of fluid surrounding the tubercular process.

EFFECT OF STRYCHNINE ON THE CEREBRAL CORTEX. — For years strychnine has been used in certain convulsive disorders, especially epilepsy, not only alone but as an ingredient in several popular formulas. Its value has been questioned by many, but it has been held to be of use by several eminent clinicians.

Recently BIERNACKI (*Therap. Monatshefte*, August, 1890) by his experiments has thrown considerable light on the action of this drug. The first of these experiments related to the action of the drug when given hypodermically. The animal was first trephined, and after waiting for the normal excitability to return, a dose of strychnia was given. It was found that a current which would produce violent tetanic spasms, would under strychnia be reduced to a faint tremor. The degree of reduction was directly dependent upon the dose employed. A second series of experiments was made, in which the strychnia was directly applied to the cortex. At first marked contraction of the vessels was produced, which soon passed off. The effect on electrical excita-

bility was the same as when the drug was injected under the skin. Compared with cocaine or morphine, when directly applied to the cortex, the effect of strychnia is very slow, it taking from twenty-seven to thirty minutes for its action to appear, and in each instance symptoms of spinal irritation appeared before the depressing effects of the strychnia. From these facts the author argues that strychnia does not directly depress cortical activity, but only indirectly by stimulating the action of the cord.

Certainly the observations are of interest, as they furnish an objective basis for a treatment that has been heretofore employed empirically.

GALACTORRHEA.—**BRAUN** (*L'Union Médicale*) recommends in excessive secretion of milk the application of a compressing bandage to the breasts, low diet, interdiction of beer, derivation to the intestine by means of a saline purgative. In case these measures prove ineffective the following mixture may be given:

R. Iodide of potassium, 2.
Syrup raspberry, 20.
Distilled water, 100.

Sig. A tablespoonful three times daily.

QUININE IN SEA SICKNESS.—**RICHERT** has recommended large doses of sulphate of quinine as a specific in seasickness. Recently one of his pupils has written him a letter (Marcel Boudovin, *Le Progrès Médical*) in which he notes the utter inefficacy of this treatment in his own case. It is to be noted, however, that Boudovin did not follow strictly the injunctions of the teacher to remain as quiet as possible in the recumbent position.

SANTONINOXIME.—This is the name of a substance prepared by M. CANNIZZARO (*Jour. de Méd. de Paris*) by the action of chlorhydrate of hydroxylamine on santonine. Santoninoxime is a white crystalline substance, soluble in alcohol and ether, but dissolving in water, whether acid or alkaline, with difficulty. C. M. Coppola has found that this substance possesses the same action in the intestine as santonine, but owing to its lessened solubility it is much less poisonous, and it should therefore be preferred to the santonine. Its dose as an anthelmintic is three times as large as that of santonine.

Medicine.

PRURITUS ESSENTIALIS.—**FEINBERG** (*Centralblatt für Gynäkologie*) describes two cases of idiopathic pruritus.

On the 1st of April, 1888, F. was consulted by a young woman, who requested that she might be given a certificate, to the effect that she was not affected with any venereal disease. The woman had been married two months, and was suffering from an intense pruritus of the external genitals and adjacent parts. The itching caused

intense mental depression. It appeared to be connected with menstruation, coming on a day or two before, and disappearing a couple of days after each period. An examination showed a pale mucosa, with abundant marks of old and recent excoriations on the external genitals. The deep mucosa was in consistence and general appearance normal, but very sensitive to the touch (hyperæsthetic). The author having excluded all other causes came to the conclusion that he had to deal with a purely nervous disturbance. He prescribed bromide of potassium internally with the application of a hot solution (1:4000) of corrosive sublimate to the external genitals. The patient improved, and he saw nothing of her until eleven months later, when he was again called and found a frightful pruritus that had extended from the pudendum almost over the entire body. This had come on during delivery; after a few days it subsided and not again return.

A second case was that of a multipara who for the past two years had suffered from vaginal pruritus during menstruation. During an abortion the pruritus had extended over the body, but it ceased as soon as the fetus was expelled. In consequence of a severe mental emotion she was taken with uterine hæmorrhage, which was followed by a severe general pruritus. Feinberg found the patient sitting on the side of the bed in great agitation, scratching first one portion of the body and then another, convinced that an abortion was about to take place.

The writer thinks that in these two cases, we have examples of nervous pruritus not dependent on secondary causes. This position is, however, negatived by some writers who think that pruritus essentialis has no existence.

ACUTE PURPURA.—**ZANETTI** (*Atti e Rendiconti della Accademia Medico Chirurgical di Perugia*) reports the case of a woman 23 years of age, who had had pains in the lumbar region and buttocks, associated with slight cephalalgia for some time. Of late these symptoms had become worse, and at the time he saw the patient intense pain had developed in the sacral region, attended by considerable prostration, elevation of temperature, (38.4 C.) hæmatemesis, sub conjunctival hæmorrhages, punctiform hæmorrhages on the arms, buttocks and neck, lenticular hæmorrhages on the belly, genitals and inner surface of the thighs. The cutaneous hæmorrhages extended rapidly accompanied by hæmaturia and metrorrhagia, followed by death from syncope on the third day. The autopsy revealed extensive sub-peritoneal hæmorrhages with extravasation into the peritoneal cavity and ventricles of the brain, intestinal hæmorrhage, spleen slightly enlarged and friable, beginning fatty degeneration of the liver.

In the absence of all signs of poisoning and of general conditions capable of explaining the multiple hemorrhages, the author arrives at the conclusion that the case is one of morbus maculosus Werloffi, notwithstanding that the course of this disease is ordinarily chronic, and the termination favorable.

CANCEROUS STRICTURES OF THE ŒSOPHAGUS.—The problem of feeding a patient in deep seated carcinomas of the œsophagus is very difficult; gastrostomy has been tried, but it is a delicate and dangerous operation, and one that can never in any way prove popular because it is not in any sense curative. The introduction of a permanent sound that shall keep the stricture dilated and through which the patient may be fed, has been attended with success. Recently an article in the *Lyon Médical*, (*Gazette Médicale de Lyon*) favors the permanent sound, claiming that it is easily introduced if done sufficiently early. The writer of this article prefers the long, soft sound with stylet to the short, hard canulas recommended especially by some German writers. The chief dangers are from hemorrhage and ulceration. The writer uses a long, soft sound that is brought out of the nose. At first it excites considerable reflex spasm and may cause vomiting, but the parts soon become accustomed to the foreign body, which then causes no further trouble.

Surgery.

BRAIN ABSCESS, APHASIA, OPERATION.—A. SANGER and C. SICK (*Dent. Med. Wochenschr. Centralblatt für Klin. Med.*) describe an interesting case of brain abscess with operation. A man 52 years of age, with left-sided chronic, purulent otitis media, had an exacerbation of his trouble—severe pain in the left ear and side of head, disturbance of the general health, pressure symptoms and disturbance of speech, characterized by forgetfulness of words and clumsiness of expression. The patient expressed his ideas frequently in writing. Later choked disc presented itself, with left facial paresis. A diagnosis of circumscribed abscess in the left temporal lobe was made. An operation was performed, and by the exploratory puncture 1 drachm of thick pus was removed from the posterior third of the left frontal convolution. After the operation the patient's speech and general condition improved. At the end of a few months the patient was apparently as well as ever, with the exception of a slight weakness of memory.

SUBACUTE CERVICAL ADENITIS OF INTESTINAL ORIGIN.—M. NICAISE (*Revue de Chirurgie*, September 10, 1890) last year attended a woman, aged 80, who suffered from a swelling in the right supraclavicular region. The skin was violaceous, tense at certain points, and on palpation obscure fluctuation could be felt. Pain was severe, and

the arms could not be moved. The swelling had lasted for three months; it began during convalescence from severe enteritis, and the patient had never regained her former health. Three separate lymphatic glands had first been affected, and they had slowly increased till they formed one tumor. At first the disease looked like simple degeneration of the glands, and it was long before any fluctuation could be felt. An exploratory puncture was made, and pus exuded, confirming M. Nicaise's diagnosis of suppurative adenitis. Then an incision was made. The pus was thick; the cavity whence it issued was tortuous. A counter-opening was made, the cavity was washed out with an antiseptic solution and drained, and covered with antiseptic dressings. Cicatrization was very rapid, although the patient was so old, and she regained her health as before the enteritis. The adenitis seemed to be a kind of critical phenomenon which freed the organism from the poison with which it had been infected in the course of the intestinal disease. Chronic adenitis of the cervical glands is not rare in old age; any other disease predisposes them to inflammation. Troisier has already pointed out that enlargements of the cervical glands are sometimes observed in cases of cancer of one of the abdominal viscera, and M. Nicaise has diagnosed the latter condition through the presence of enlarged lymphatics in the neck.—*Brit. Med. Jour.*

Obstetrics and Diseases of Women.

IMMEDIATE REPAIR OF THE PERINEUM.—T. H. HANCE, M.D., in a paper read before the New York Academy of Medicine, advocated the immediate repair of injuries to the pelvic floor, where the laceration had not extended through into the rectum, that is, in cases where there was either a clean cut through the perineum, or through the skin and perineum to one side or other of the median line. In those cases where the posterior vaginal wall had been ruptured without laceration of the skin, the operation also offered good results. He thinks that there ought to be no difficulty in recognizing these incomplete lacerations at or just before delivery (by digital examination) thus gaining time to make preparations to repair them at once. He introduces the first suture high up in the vagina above the tear, in order to avoid the formation of pockets; he also thinks that this method offers the best results for the restoration of the pelvic floor. If the laceration has extended up on both sides, they are to be repaired separately. The patient's legs are kept tied together for twenty-four hours after the operation, and the bowels are moved on the third day. He says that two points ought to be closely observed in order to insure success, that is the careful adaptation of the lips of the wound, numbering the sutures to individual requirements; and secondly, the observance of strict antiseptic pre-

cautions, including the use of antiseptic douches before and after the operation, antiseptic pad, etc.

All members taking part in the discussion expressed themselves as in favor of immediate operation.—*Archives of Gynecology*.

TREATMENT OF INOPERABLE UTERINE CARCINOMA WITH CHLORIDE OF ZINC.—HABERLIN (*Correspondenz-blatt für Schweizer Aerzte*) recommends the use of a paste composed of chloride of zinc. He agrees with Meyer, Schroeder and Leopold that the total extirpation of the carcinomatous uterus presents about all that is required for an operation both in its effectiveness and mortality, he also agrees with Leopold that in the cases in which we have a recurrence, the disease is milder and more easily endured. It is, however, in those cases in which the cancerous process has affected other organs and a certain amount of affected tissue must be left that it is well to study the effect of other remedies. He places the mortality of these cases at 20 per cent. or over. Kaltenbach claims that even where a considerable portion of the morbid growth is left an operation is still justified, as, by that means, the pain, discharge and itching are lessened, while sleep and appetite are improved, thus rendering life more endurable. The same result can be achieved by a less bloody and safer operation, which may be employed in cases in which total extirpation is out of the question.

The author gives the histories of five patients that amply attest the correctness of his views. They were all treated by the application of chloride of zinc paste, and in each case there was marked amelioration in the local symptoms and improvement in general health. In only one case did severe hæmorrhage follow, and that was one in which the patient was allowed to leave the clinic before cicatrization was complete. Discharges were greatly lessened in each case, and in some they ceased entirely.

Chloride of zinc has been used in the form of solution and as paste. A. Martin tried as early as 1879 the paste recommended by Labbé (chloride of zinc and starch, equal parts). Vohwinkel used a similar mixture composed of chloride of zinc four parts, farina three parts, oxide of zinc one part. Ely van de Warke in 1884 recommended solutions of 30 and 50 per cent. From the observations of Ehlers it is clear that the proper localization of the remedy is very difficult if it is in solution. For these reasons the writer has confined his experience to the use of a paste which is made by rubbing equal parts of chloride of zinc with a small quantity of water. A quantity corresponding to the defect to be treated is placed upon a cotton tampon, and carried into the cervix. To fix the tampon and protect the vagina iodoform gauze is placed about the cervix. The time that the tampon is allowed to remain

varies according to the reaction: after it is removed the vagina is irrigated with an antiseptic solution. The technic of the operation is of the simplest.

What is the danger of this operation? A. Martin has observed cauterization of the bladder, rectum and perforation of the peritoneum: one patient died from hæmorrhage. The author's patients have for the most part borne the operation well, notwithstanding the cauterizations have been very energetic; it is naturally difficult to determine just how deep to go; but they have been governed to some extent by the amount of pain produced; if greater than could be overcome by an injection of 0.01 of muriate of morphia, the tampon is removed, when if it is found that the action has not been sufficient, it is again renewed.

Five to eight days after the application of the paste, a thick 5 mm. eschar separates, leaving a granulating surface that bleeds, when touched, but not spontaneously. While the theory of Van de Warke that zinc chloride has a specific action, in that it coagulates carcinomatous tissue, and produces an inflammation in normal tissue, has been negated by Ehlers, yet it is equally true that it is the very best cauterant that can be used, as no other produces so perfect an eschar.

The writer closes with the following sentences: "In cases of carcinoma where all of the diseased tissue cannot be removed the hope of improvement is very slight as compared with the dangers of the operation. My own cases, while few in number, prove that we have a simpler and less dangerous method in these doubtful and certainly inoperable cases, from which the most favorable results may be expected. While we exclude total extirpation as a palliative measure, we must not stand with our hands in our laps, but begin a careful palliative treatment in the use of chloride of zinc that is capable of giving to these patients many comfortable days, even when the circumstances are relatively unfavorable."

Ophthalmology.

A CASE OF DOUBLE SIDED HEMIANOPSIA.—FÖRSTER (*Jahres-Bericht der Schlesischen Gesellschaft für vaterländische Culture*, 1890) describes the case of a postal secretary who had suffered from right hemianopsia for four years without any disturbance of the general health. The dividing line between the defective and functionary halves of the visual fields was in a vertical meridian, though it deviated about 2° toward the right or affected side. The patient had continued his occupation notwithstanding the visual defect, but in August, 1886, he, in the course of three days, lost vision in the left half of the field, also without any disturbance of the general health. In November the patient when moving presented the appearance of one totally blind. Examination showed a visual field of 3° horizontal and 2° ver-

tical, at the fixed point, with acuity of vision about one-third. Four months after the second attack the papilla optica did not present a trace of atrophy. Optical memory was good, though the color sense was completely absent, as was the ability to grasp or reproduce topographical conditions (*topographische Vorstellungen*)—this last defect was so great that the patient after some weeks was not orientated in his own room; further, he was unable to reproduce the boundaries of countries or the routes that he had frequently traveled. The author regards the condition as due to a thrombus of the cortical vessels. The deviation of the dividing line towards the defective side which is often observed in hemianopsia, he attributes not to a mixing of the nerve elements at the fixation point, but to a richer blood supply in the cortex corresponding to the greatest acuity of vision. The case further teaches that in the occipital lobe we have the seat of the topographical remembrance and not that of visual memory.

THE CORROSIVE-SUBLIMATE TREATMENT OF GRANULAR CONJUNCTIVITIS.—The treatment of different forms of granular conjunctivitis with various strengths of corrosive sublimate solution seems to have given good results in the hands of Guaita (*Annales d'oculistique*). The details of the treatment are published in the *Union Médicale*. The sublimate is used in strengths of from 1 to 300 to 1 to 500, and is applied to the palpebral conjunctiva with a camel's hair brush every two hours, or according to the severity of the case. If the disease is slight, a collyrium of 1 to 1,000 is given. There have been no symptoms of poisoning or complications to the cornea from this method, but very prompt amelioration of the symptoms has followed its employment in every instance.—*N. Y. Med. Journal*.

Physiology.

INVESTIGATION ON THE SENSE OF TASTE.—OEHRWALL (*Skandin. Arch. f. Physiol.* II, p. 1, 1890) like other observers, recognizes four kinds of taste, namely, sweet, saline, bitter and acid. There does not seem to be any transition between these four varieties, so that the author regards the differences between them as those of modality, and not as qualitative differences of one sense. When cocaine was applied to the tip of the tongue the sensibility for adequate stimuli, that is, sapid bodies, disappeared, and even the electrical current failed to excite a sensation of taste. It is remarkable, however, that there remained only a sensation of heat or cold. The chief part of the communication deals with punctiform stimulation of the individual papillæ by means of fine brushes. There are marked functional differences amongst the papillæ. The fungiform papillæ are excessively sensitive to tactile, thermal, and cold impressions, so that by simply

touching one such papilla a very complex sensation results, first that of contact, nearly simultaneously cold, and then the taste sensation follows. Electrical stimulation may excite acid or other tastes. Goldscheider and Schmidt have also investigated this subject (*Centralblatt f. Physiol.*, vol. iv, No. 1, 1890). They find that certain parts lying between the papillæ do not excite the sensation of taste, and that the several papillæ are not all equally capable of exciting the several tastes. In many individuals the taste of "sweet" alone is developed near the middle line on the hard and soft palate. Acid tastes are less developed in the circumvallate papillæ than on the anterior part of the tongue. At the anterior part of the tongue only the tip and sides seem to excite taste. The so-called alkaline taste excited by a constant current seems to be a composite result, due to a mixture of bitter and saline tastes with stimulation of sensory nerves as well. Between the papillæ there is never any sensation of taste. It is possible to fatigue the papillæ for one taste, for example, the circumvallate papillæ may, by repeated application of quinine, cease to detect bitter, while still capable of responding to sweet substances. Stimulation with acid, however, diminishes the excitability for all stimuli. It would seem from these researches that there are four different kinds of gustatory sensations—bitter, saline, acid, and sweet; that each seems to be related to a special form of peripheral end organ, and that the papillæ are supplied in different proportions with these several fibres or nerve endings, so that it appears that the doctrine of the specific energy of nerves is also applicable to the sense of taste.—*British Medical Journal*.

Bacteriology.

PASTEUR INSTITUTE OF PARIS.—In the October 19 issue of the *Journal de Médecine de Paris*, three deaths were reported to have taken place after the preventive inoculation.

On the 6th of September last, in Ile sur-la-Tet, arrondissement of Prades, a mad dog bit Jean Domenech, 7 years of age, and Sebastian Vidalon, aged 46 years, the last having had his lips and part of his face torn away by the fangs of the enraged animal. The department sent both patients to the Pasteur Institute, where they were treated, and returned home apparently well. A letter from Perpignan under the date of October 10 states that both unfortunate victims had died after the most atrocious suffering.

A little citizen of Guyotville, 14 years of age, had been at the Institute for one month in consequence of a bite received September 8. He died the morning of the 12th of October, after a night of horrible suffering. The wound had not been cauterized, and the boy presented himself for treatment five days after receiving the bite.

SATURDAY, JANUARY 10, 1891.

THE SURGICAL TREATMENT OF LARYNGEAL
TUBERCULOSIS.

Surgical intervention in certain cases of tuberculosis of the larynx marks an epoch in laryngology. When HERYNG, of Warsaw, and KRAUSE, of Berlin, first promulgated their methods and results, laryngologists were generally skeptical. They bethought themselves of the numerous instances of conjoined laryngeal and advanced pulmonary tuberculosis in whom to scrape and inject, to cut and cauterize, seemed unnecessary and even cruel.

But other, more sthenic cases exist, with whom the lungs are "not appreciably" or but slightly infiltrated, without fever and cachexia—patients otherwise capable of resisting the attack of the bacillary monster, at least for years, but for a laryngeal complication.

At times the deposit of tubercular foci excites the laryngeal epithelium to proliferative activity, producing mammillated or villous neoplasia-toid projections, which cover by preference the inter-arytenoid region, but which may extend to other parts of the larynx, and so encroach upon its lumen as to present a choice only between intralaryngeal surgical intervention, tracheotomy, or death hastened by *dyspnea*. Again, tuberculous ulceration, especially of the epiglottis or arytenoid region, by rendering deglutition excruciatingly painful, may present the alternative only of surgical intervention to promote healthy cicatrization or death hastened by *dysphagia*. To these graver complications, *dyspnea* and *dysphagia*

may be added also *aphonia* as a third indication for the surgical method. Nor need the actual presence of such distressing states be awaited, but one should operate also in the early stages, on the principle of prophylaxis.

By "surgical treatment" is meant the removal of exudative and proliferative material by the curette, cutting forceps, or punch, and the *curettement* of tuberculous ulcerated areas, each followed by the application of lactic acid as a mild escharotic, which is believed to exert a specially favorable influence in promoting cicatrization. The mere application of lactic acid without previous preparation by incision or scraping of the part, is not conceded to be within the scope of the term "surgical," although a 60 to 100 per cent. lactic acid solution alone, may suffice when the ulcers are already well exposed.

The many papers and discussions before the Sections of Laryngology, respectively, of the Tenth International Medical Congress and the recent meeting of the British Medical Association, witness the importance of this subject. At Berlin, HERYNG, STORK and SCHEINMANN spoke favorably of the method, and KRAUSE exhibited cases apparently cured. At Birmingham, Mr. CHARTERS J. SYMONDS, of Guy's Hospital, read the opening paper. He approached the subject from the standpoint of a surgeon having to deal largely with the eradication of tubercle from joints, bones, skin, etc., and while recognizing the greater difficulties surrounding operative interference in the larynx, parts of which are not readily accessible, he held that with skill, and the instruments now in use, these difficulties could be surmounted.

In opening the discussion Dr. G. HUNTER MACKENZIE, whilst deprecating heroic measures in individuals with extensive pulmonary participation, advocated in suitable subjects, the surgical removal of papillomatous or exudative material and the stimulation of ulcers to more healthy action by lactic acid, menthol, or iodoform, although he asserted, from prolonged experimentation, that the action of these agents upon the bacilli was absolutely *null*, and believed that they were not superior for the purpose to chloride of zinc, carbolic acid, and other materials. Mr. LENNOX BROWNE insisted that it was important to apply the lactic acid with some friction and that the surgical treatment was then ben-

eficial in cases of ulcerations and granulations peculiar to the chronic stage of this disease.

In estimating results it must not be forgotten that laryngeal disease in tuberculosis, may be tubercular, non-tubercular, or mixed. Such patients are prone to simple laryngitis, and non-tuberculous exudation and even superficial ulceration can ensue, which, of course, would readily heal. Further, that spontaneous cicatrization of real tuberculous ulcers has been observed.

But with all due allowance, the cases in which either material amelioration or a local cure has been induced by the observers mentioned, as well as by GOUGHENHEIM and LUC, in France, justify the following conclusions:

That the surgical treatment of laryngeal tuberculosis may be advantageously undertaken:

1. In all cases in which there is little or no evidence of pulmonary disease.

2. In those accompanied by dyspnoea, dysphagia, aphonia, or severe cough, with existing but not rapidly advancing pulmonary participation.

That asthenic cases of conjoined laryngeal and advanced pulmonary tuberculosis ought not to be subjected to violent local treatment, but should receive only mildly stimulating and sedative applications in the form of sprays, powders or pigments.

CHLOROFORM VERSUS ETHER.

The report of the Hyderabad Commission on this subject is doubtless fresh in the minds of our readers. It will be remembered that the unanimous conclusion of the members of that body, after very elaborate investigation, was, that in death from chloroform respiration always ceased before any dangerous failure of the heart took place, and that its effects were precisely similar to those of ether, except that the dose of ether needed to be much larger. Naturally, a view of the subject so opposed to the opinions of a large proportion of the profession could not be expected to meet with immediate acceptance, and, as a matter of fact, it was quickly controverted in various quarters. An important contribution to the subject has just been made by DR. J. A. McWILLIAMS, in a report to the Scientific Grants Committee of the British Medical Association, published in the *British Medical Journal*, which

goes far to show that the conclusions of the Hyderabad Commission are not applicable to all animals, and that there is some ground for the belief, heretofore widely held, that chloroform has, in some cases, a pernicious influence on the heart that is not shared by ether.

Dr. McWilliams began his experiments in 1888, at a period, therefore, long before the report of the Commission, and continued them at intervals down to a recent time. The animals employed were principally cats, and the aim of the investigation was specially to observe directly the effects of the drugs upon the heart. For this purpose, the chest was opened, under suitable precautions against hæmorrhage, and an automatic recording apparatus attached to the heart, artificial respiration and the administration of the anæsthetic being effected by means of a bellows connected with a canula inserted in the trachea. By this means, it was possible to watch the action of the heart during the experiments, while the circulation went on undisturbed, except for the effects of the drugs administered. It was found that dilatation of all the cavities of the heart frequently occurred under the influence of chloroform, at an early period, in many cases before the cornea became insensible, and without interference with the regularity of the heart's action. This was usually associated with a fall of blood-pressure, but bore no constant relation to it. In some cases a periodical depression of the ventricular action was also noticed. Neither of these effects was observed from the administration of ether, even when pushed to the extent of completely abolishing the conjunctival reflex. In many cases the drugs were repeatedly administered, alternately to the same animal, with the result that dilatation of the heart uniformly took place under chloroform, and was as uniformly absent, with an equal or greater degree of anæsthesia, when ether was used.

To meet the objection that these results might be in some way due to the opening of the chest, chloroform was, in a number of cases, given in the ordinary way, and the chest quickly opened, when the heart was found dilated, as in the other experiments.

In three cases cats became suddenly collapsed during the administration of chloroform preliminary to the insertion of the canula, while natural

respiration was going on regularly and efficiently. The pulse was found, in each case, to be imperceptible, and, after respiration had gone on for some time, the heart was found, in each case, on opening the chest, to be contracting so feebly as to be entirely ineffectual in propelling the blood. All the animals were resuscitated by rhythmic compression of the heart with the thumb and finger. As a general rule, however, in death by chloroform, respiration ceased before any such failure of the heart's action as to be incompatible with life.

It was found that, with a given proportion of chloroform in the inspired air, changes in the rapidity of respiration had a marked effect upon its absorption. An amount of chloroform that could be given with safety during quiet respiration, speedily produced alarming symptoms when respiration became rapid and deep.

The most effectual way of increasing the blood-pressure in the carotid, when it had fallen to a dangerous degree, was found to be firm compression of the abdominal aorta.

The practical bearing of these facts is obvious. The value of such investigations as those that led to their discovery is equally so. Among the thoughts which they suggest is the question how soon such researches will be carried on with funds contributed by the American Medical Association.

KOCH AND HIS CRITICS.

In the blame which has, in various quarters, been freely bestowed on the man who is, just at present, the most prominent figure in the medical profession, for not at once making all the details of his discovery public, the important circumstance has been ignored that he does not seem to have been altogether a free agent in the matter.

DR. KOCH is a salaried officer of the German government. The Hygienic Laboratory, in which his researches have been carried on, is supported by public funds, and the investigations themselves were a part of the work for which he is paid. Under such circumstances, it would not be merely politic, but eminently fitting, that, as long as he retains his office, he should pay a good deal of regard to the wishes of his official superiors. There have been reports that it was in def-

erence to pressure from that quarter, and against his own judgment, that he made his announcement in the International Medical Congress. However that may be, the Minister of Public Instruction, GOSSLER, stated, in reply to an enquiry made of him in the Prussian Diet, that Koch's wish was to publish all the details, but that, on account of the difficulty of preparation of the remedy, and the harm that might result from the use of imperfect and irresponsible imitations, he had prevailed upon Koch to defer publication of its nature, a step for which he assumed the entire responsibility.

Of the necessity of such a course probably no one can be a competent judge who is not acquainted with all the reasons which led to the decision. No one can doubt that if the method of preparing the remedy were made public, the markets of the world would soon be flooded with the products of competing manufacturers, some of whom might not be able, with the best disposition in the world, to judge as to the quality of their wares. The tests which have been made of various brands of pepsin may serve as an illustration of the varying quality of articles going under the same name. It is of the utmost importance that the remedy shall be tested in such a way as shall be conclusive in regard to its value, and the gratification of a legitimate curiosity is of very little moment in comparison. Whatever may be thought of the reasons for secrecy in this case, the responsibility for it should be placed where it belongs, and that is evidently not with Dr. Koch, but with his superior officer.

IMPORTANT PRELIMINARY WORK.

But four months intervene before the Annual Meeting of the Association at Washington. Those most interested in its welfare need not to be advised that the value of these annual meetings lies not so much in the work accomplished in General Sessions as in that which is done in the Sections. By the quality of Sectional work the real value of the Association must be estimated. By this its future success or failure will be assured.

The Association is especially fortunate in the selection of its officers which are to supervise the work in the various Sections for the coming year. In each department men of ability, and whose work in the past is a guarantee of success, are in

command. To these we look for that thorough preliminary preparation which is absolutely essential. To this end THE JOURNAL will venture a few brief suggestions:

1. To determine as nearly as may be the number of papers which can be properly presented and discussed in a given Section during the several sessions of the Annual Meeting. 2. That men specially qualified for the work be secured in sufficient number to prepare the papers which shall meet this requirement. 3. That the attention of each writer be called to the fact, that papers submitted to the Sections become the property of the Association for its exclusive use, and are not at the option of the writers, for publication elsewhere. 4. That all papers be fully completed when they are presented, and pass immediately from the readers to the Secretaries of the Section in which they are read.

The papers thus prepared and submitted will determine the value of the "Original" department of THE JOURNAL to its readers for the coming year. By these papers the status of our Association is justly to be adjudged not only by the profession at home, but also in other lands. We know that those upon whom the responsibilities rest are fully equal to their work, and we confidently anticipate that the programme for the present year will exceed any one that has gone before.

SHALL "THE JOURNAL," BE REMOVED TO WASHINGTON?

Thus far but a limited number of replies to this question have been received. It seems desirable that the reasons for and against such a movement should be fully stated. If possible the wishes of the entire membership should be known, and in the settlement of the question, the will of the majority should govern.

If possible the question should be promptly and permanently decided at the next Annual Meeting, and in such manner as not to divert the attention of the members from the important work in the Sections, nor trench upon the time allotted to them.

The views of the members upon this question should have full expression before the Annual Meeting, and with positive conviction upon that subject it need not require any considerable time to come to definite conclusions.

In the meantime let the reasons for and against removal be carefully considered, and in the order in which they may be forwarded for publication THE JOURNAL will present them to its readers.

EDITORIAL NOTES.

A COMING VACANCY IN THE U. S. A. MEDICAL DEPARTMENT.—The single colonel of staff who retires in 1891, by reason of age limitation, is Dr. Edward P. Vollum, who is stationed in New York City, and acting chief medical purveyor, pending the Senate's confirmation of his appointment last August. He was candidate for the surgeon-generalship after Dr. Baxter's death. He is a New York man with a long, active record, and is at present president of the Army Medical Board in that city. His original commission is dated May 12, 1862. He retires on September 11.

FORTY-FIVE DAYS OF FASTING.—Succi had rendered himself famous in London by a fast of forty days, which he completed in May last. Later he came to America. On November 15 he commenced a fast of forty-five days, in New York City, completing the same December 20. At the commencement of the fast his weight was 147¼ lbs., at the end of the forty-five days he had lost 42½ lbs., or nearly one pound for each day. At the conclusion, the final medical examination, his condition is reported as follows: temperature normal; pulse 62; respiration 90 (?); dynamometer 44; tongue clear, moist and steady; general condition weak; urine eight ounces in twenty-four hours; specific gravity 1.022; reaction acid, clear. Of drinks during the forty-five days he took 291 ounces of croton water; 799 ounces of mineral water, and 64 ounces of ice. Of his elixir, which is composed of morphia, cannabis indica, chloroform, sulphuric ether and alcohol, he took during that time 710 drops. His sufferings during the last few days were intense, and when the forty-five days were ended he had reached the limit of his endurance.

UNOSTENTATIOUS CHARITY.—A resident of Lowell, Mass., whose name is withheld, has pledged \$25,000 towards the new free hospital to be established there. A board of officers was elected on the 29th ult.

DEATH FOLLOWING INOCULATION FOR LUPUS.—According to the *Wiener Klinische Wochen-*

schrijf, a girl 17 years of age died after an injection of two milligrams of Koch's lymph. The injection was made at 9 A.M.; at 3 P.M. the characteristic appearances were observed upon the affected portion of the face. The local manifestations were more and more pronounced. The bright red zone became more and more livid; dyspnoea and heart failure ensued and the patient died thirty-six hours after the injection.

DR. MILAN BAKER, a graduate in 1855, of the Medical Department, University, Buffalo, N. Y., and an original member of the New York State Medical Association, died at his home in Buffalo, December 29th last, aged 62 years. He was a member of the original commission which located the State asylums for the insane, and at the time of his death was one of the managers of the State insane hospital in Buffalo.

SPURIOUS KOCH'S FLUID.—It is already reported that spurious Koch's fluid is being manufactured in Berlin, and that medical men are being deceived in their effort to secure the genuine article. There hardly seems a limit to the deceptions which will doubtless be attempted in this direction, and the medical profession will need to be everywhere on the alert to protect the people from the evil to be averted, and from the frauds which unprincipled venders may seek to perpetrate.

QUARANTINE AGAINST CHOLERA.—The suggestions of Dr. J. H. Rauch, Secretary of the Illinois State Board of Health, upon this subject are timely, and should receive most careful consideration. He predicts a serious invasion of cholera, unless efficient quarantine regulations are adopted. In Abyssinia 10,000 people have died of cholera during the last six months. In India it is epidemic. It is not yet extinct in Spain. In the Asiatic provinces of Russia, in Corea and Japan, 80,000 people have recently died of this disease, and he urges that our Pacific coast be especially subject to the strictest of quarantine supervision.

UNWARRANTABLE JEALOUSY.—It seems incredible that such an intensity of hatred should be manifested on the part of German physicians as that they should seek to prevent so eminent a man as Morell Mackenzie from obtaining a reasonable supply of Koch's fluid for the purpose of

testing its alleged virtues. Medicine and the alleviation of human ills are supremely above the petty differences and jealousies of men, and the effort thus to control the use of the lymph for the gratification of petty or personal spite, is unworthy of the most degenerate member of the profession, either in Germany or elsewhere. For the good name of the profession in Berlin we sincerely hope that the charge is totally untrue.

DR. CHARCOT, who has recently finished a long series of experiments with hypnotism, gives as his opinion that not more than one person in 100,000 would be likely to be benefited by this mode of treatment.

DR. ERNEST HARDY.—*Le Progrès Médical* of September 27 contains an account of the death of this eminent scientist. He was a member of several important medical and scientific bodies and contributed many important monographs, especially those upon the physiological actions of jaborandi and strophanthus.

"CONFRATERNITE."—Under this heading *Le Progrès Médical* describes an incident occurring in the town of Fehrltorf. A citizen of the place having trouble with his foot, three physicians were called in who decided that an amputation was necessary; a Doctor Ries undertook to cure the foot without an operation, and the patient dying, he wrote upon the death certificate, "Dead from the bad treatment of the physicians." He further declared that his colleagues were ignorant of surgery. For this and the monumental death certificate he was compelled to pay 1,200 francs damages. It is only in this latter part that they do these things better in France.

THE GERMAN GOVERNMENT AND KOCH'S MATERIAL.—After going to press we received the following cable from Dr. Harold Ernst, in Berlin, under date of December 10: "The secret of making Koch's material has been turned over to, and kept by the German Government only until a thorough trial can be made. The effect in lupus and surgical tuberculosis is most striking, because the results can be seen. The most wonderful property is the selective affinity for tuberculous nidus, often making latent centres active. Pulmonary tuberculosis will have to be under observation for a long time still before permanent result is determined. The action of the material is certainly as wonderful as that of any known medicine.—*Boston Med. and Surg. Journal*.

TOPICS OF THE WEEK.

RESEARCHES ON MALARIA.

So much importance is now attached to the action of bacteria upon the system in the production of disease, that we need not apologize for placing before our readers the results of the researches of Dr. Bernardo Schiavuzzi on malaria in Pola, which seem to have culminated in the discovery of one at least of the microorganisms that are capable of inducing ague. Pola is an ancient city of Istria, on the east coast of the Adriatic, long decaying, but now again rising in importance as a naval station, built on chalk, on which is a stratum of red earth, about 9 feet thick, which is of submarine volcanic origin, and was cast up in the miocene period. Its isotherm is 14.17° C., with wide extremes, its yearly rainfall amounts to 937 mm., whilst its physical conditions are favorable to the development of malarial fevers, which are endemic.

In the year 1866, Dr. Salisbury believed he had discovered the cause of malaria in an alga of the group of palmella, to which he gave the name of "palmella gemmascina," and which he had found in some of the marshy districts of Ohio. In 1869, Balestra examined the waters of the Pontine marshes, and satisfied himself that an alga which he named "alga miasmatica," and which was either an oedogonium or a cladophora, was the active agent in producing ague. Salisbury grounded his belief on the circumstance that a young and healthy couple sleeping in a room with a few boxes containing this alga were attacked with malaria, whilst Balestra induced an attack in himself by smelling some water containing the alga miasmatica. Safford and Bartlett, Archer and Barzellini, severally called attention to the probability of various algae being the active agent, but only on the ground that such algae were abundant in malarial regions; and objections were raised to their statements when further investigations showed that in each instance the alga in question was abundantly present in perfectly healthy regions. In 1873 Griffini injected into the veins of dogs and rabbits the dew which he had collected in marshy grounds and paddy fields; but though the temperature of the animals rose a degree or two, the spleen remained unaffected, and health was soon restored. Lanzi and Ferrigi were led from their inquiries to think that the malarial poison was the product of some kind of vegetable decomposition; and experimenting with the mud of the marshy districts of Ostia, which they injected into the vessels of guinea-pigs, they observed a rise of temperature to 40° C., enlargement of the spleen and liver, and the presence of pigment in these organs and in the blood. After the meeting of biologists in Kassel in 1878, Klebs and Corrado, and Tommasi-Crudeli examined by means of special apparatus the air, the water, the mud and the earth of the Campagna, and endeavored to cultivate the algae naturally present. They obtained a great number of minute bacilli with fine fibres, small rounded granules like micrococci, and other microorganisms, which they carefully cultivated; whilst they at the same time made anatomical investigations on the size of the spleen in healthy

white rabbits; then, having inoculated the animals, they arrived at the conclusion that they had discovered the malarial poison in a schizomycetous fungus, to which they gave the name of "bacillus malaric." In 1880 Tommasi-Crudeli, Cuboni, and Marchiafava repeated and confirmed these observations, since they could produce an affection similar to or identical with the malarial fever with this bacillus, and because they found numerous similar bacilli together with roundish, highly refractile granules or spores in the blood. The spores were contained in large numbers in the interior of the white corpuscles. They presented lively oscillating movements, and became more numerous, whilst the bacilli were fewer, as the temperature of the animal increased. In 1881 Laveran made a special study of the pigmental bodies which are found partly free in the blood plasma of malarial patients, and partly embedded in clumps of protoplasm or in white corpuscles, and arrived at the conviction that they were parasitical elements in various stages of development and decay.

Schiavuzzi's experiments extended over several years, and consisted in obtaining pure cultures of a bacillus, which he found abundantly present in the air of Pola, a place where malaria is endemic, and which agreed in its characters with that described by Klebs and Tommasi-Crudeli. With this he infected rabbits, and in the memoir he has just published in Cohn's *Beiträge zur Biologie der Pflanzen* he gives charts of the temperature and figures copied from photographs of the bacilli he found in the animals. The bacillus is rarely present in the waters of the endemically affected district. It is aerobic, and develops on the surface of nutritive gelatine in the form of a whitish and tolerably resistant coat. Infection of this bacillus produced intermittent fever in tame white rabbits of the tertian and quotidian types, but without pernicious character in any case. It occasioned enlargement of the spleen and formation of the characteristic black pigment in the spleen and in the abdominal glands, and the blood corpuscles presented the changes shown by Marchiafava and Celli to be pathognomonic of malarial infection; whilst a development of bodies exactly resembling the spores of the bacillus took place in the blood. From all these circumstances Schiavuzzi and Tommasi-Crudeli, who fathered Schiavuzzi's memoir at the meeting of the Academy dei Lincei, entertain no doubt that the bacillus malaric is the active agent in causing intermittent fever. The care with which these experiments were made is deserving of great credit. In each experiment the following details were attended to: The precise spot from which the air was obtained, with its height above the sea level; the date; the reading of the barometer and thermometer; the direction and strength of the wind; the relative moisture of the air, the actual amount of moisture it contained; the reading of the heliograph on the day when the specimen was obtained; the amount of ozone in the air; the rapidity of evaporation; and the temperature of the earth. The statements require confirmation; but the etiology of malaria may now be referred with tolerable certainty to the growth and development of a microorganism of vegetable origin in the system.—Editorial, *Lancet*.

MEDICAL CLASS IN JAPAN.

The following appears as an editorial in *The Sei-i-Kawai Medical Journal*, published monthly in Tokyo, Japan, under date of Nov. 22, 1890:

We may fairly divide the medical profession in Japan into four classes viz.: 1. *Kunpo-ka* (Chinese school), 2. *Kan-ran settu-ka* (China-Dutch school), 3. *Seiyo-ka* (European school), 4. *Seimon-ka* (specialist).

Those who belong to Chinese school are old in age, most of them over 50 years, and got the license by virtue of professional tradition from their forefathers; their knowledge consists of reading Chinese pseudo-physics; they have never seen the inside of human subject nor use any instrument for the aids of diagnosis. Their medicines compose of herbs, barks, and roots of various plants which are always given as decoction and prescriptions of some coarse minerals are seldom used.

Their numbers at present overrate than the other classes and show figures of at least 20,000 out of 40,000 whole number, but their numbers are decreasing year by year as they either die or retire on account of their old age, as were stated before, and they never have chance to grow up, because the present system of granting licentiate is strict and candidates must pass a hard examination. Those belonging to China-Dutch school are mostly over middle age; they have studied Chinese medicine, but the event of intercourse with Dutch nationality provoked them to study Dutch medicine as well; in those days they could not read Dutch books, and those very few people who could hardly understand them endeavored to translate them into Japanese, by means of that, most of this class possessed an outline of European medicine, but their knowledge is quite stale nowadays, having passed 30 to 35 years.

Their numbers are about 10,000 and their licenses were granted exactly in similar way as that of Chinese class. They treat patients much in similar manner as Chinese school, but often use mixtures, pills or powders which contain one or more drugs, such as opium, calomel, iron, soda, assafoetida, aloe, santonine, etc. Indeed we owe much the progress of European medicine in Japan to encouragement of certain persons in this class.

Moreover certain number of this class followed the progress up to present by their indefatigable energy, and they hold high reputations and respects both in private and public works.

The third class belong to European school (*Seiyo-ka*); they have undergone a good education either in university, colleges or schools properly instituted under the inspection of the government, their numbers do not exceed more than 5,000 including those who have studied medicine in Europe or America, indeed the reformation of Japanese medicine is the task of them, for this object they join to constitute medical societies and respective society endeavors to publish their journal. The chairs of university, and of colleges are occupied by the members of this class, and the surgeons of Imperial Navy and Army are chosen amongst this class, indeed the important situations both in public and private are entirely held by them. Instead of their honors and reputations they are burdened with a heavy obligation that is for the

welfare of future medicine of Japan, to meet these obligations, for instance they started some years ago the Private Sanitary Association of Japan, and carried their works to a great satisfaction both to laymen as well as the professional; moreover the principal leaders in Tokyo caused themselves to start a medical association for the object of which they have to gather all the medical brethren in every province of the Empire and to exchange their knowledges.

The endeavor of them brought this scheme to born in April last under the name of the First Japanese Medical Association, the meeting was held in Tokyo for a week and was closed with every success. It was hoped to hold this association in future once every four years.

The 4th class belong to specialist, viz.: oculist, obstetrician, dentist, bonesetter, vaccinator, etc. Some of them are well educated under the new school, but most of them follow the profession by the tradition and could not be called specialist under the proper sense.

THE RISKS OF KOCH'S TREATMENT.

In the very interesting communication from our Special Commissioner at Berlin reference is made to the dangerous symptoms which may attend the use of injections with Professor Koch's liquid; and although he explains the fatality in some of the fatal cases to be due to the ordinary course of the disease under treatment, there can be little doubt that in a few regrettable instances there has been evidence of disastrous results. The fact is, the profession have been placed in possession of a most powerful poison, and that as yet experience of its effects—which, like all poisons, vary in individuals according to their special idiosyncrasies—is so small as to necessitate the utmost cautious employment of it; this, too, quite apart from cases of pulmonary and laryngeal tubercle, where the local reaction set up by it may of itself produce alarming and dangerous symptoms. Therefore we endorse fully our correspondent's view as to this being an agent (and it is still to be proved that its action is curative) which should not be employed in general practice, but only under circumstances admitting of the strictest continuous medical surveillance. A like conclusion is stated in the excellent report drawn up by Drs. Saundby, Simon, and Barling—*Birmingham Medical Review*, December, who urge the greatest circumspection in dosage and conditions of administration. We believe, for example, that it is rash to commence the treatment of lupus with as much as 0.01 grm., as recommended by Professor Koch, the severity of the local and general reaction being in many cases so extreme.—*Lancet*.

L'UNIVERS MEDICAL.

A new journal, with the title *L'Univers Médical*, is about to appear in Paris under the editorship of Dr. Séxéno, a pupil of Dr. Apostoli's. It is understood to be an outcome of the Berlin Congress, and will have for its object the promotion of professional solidarity among medical men of all countries, and the furtherance of international coöperation in matters of hygienic reform.

PRACTICAL NOTES.

TRENDELENBERG'S FLEXIBLE DRESSING.

Prof. Trendelenberg has been using at his clinic a gelatin paste, recommended by Unna, that is designed to be substituted in those cases where flexible collodion or india-rubber solutions have formerly been employed. It will hold dressings in place while permitting free motion of the parts. It is not friable nor very stiff, and is not so adherent to the cuticle as to interfere with the excretory functions of the skin. It therefore does not cause the peeling off of the upper layers of the epidermis, upon being removed, and the tendency to eczema in consequence. It is prepared in two degrees of consistence: the thick paste contains gelatin, glycerine and water each thirty parts, with oxide of zinc ten parts. The thin paste has gelatin twenty parts, glycerine thirty, water forty, with oxide of zinc ten parts. Heat is necessary when the pastes are compounded; it is also needed to liquefy them when they are used. The pastes are readily removed with warm water.

ICHTHYOL IN GYNÆCOLOGY.

Ichthyol is strongly recommended by Dr. Freund in the treatment of inflammatory diseases of the female genital organs. Its action is superior to that of all other remedies hitherto in use. Locally, it acts as an antiseptic and analgesic; internally, it improves the general health, increases appetite, improves digestion, and regulates the action of the bowels. Dr. Freund has treated with success cases of chronic parametritis, chronic and sub-acute perimetritis, chronic metritis, salpingitis, erosions of the cervix, cicatrices of the vagina, and prurigo of the external genitals. He prescribes its internal and local use simultaneously.—*L'Union Médicale*.

TREATMENT OF HÆMORRHOIDS BY COLD WATER.

The treatment by very cold water of hæmorrhoids is advocated anew by Dr. Alvin, in *La Semaine Médicale*. His method is the simple one of applying the water to the anal region by means of a sponge, but the method will not succeed unless the sponging is kept up for a number of days. If this is done the growths will diminish in size, and there will be a general relief of the ordinary unpleasant symptoms, such as pain, tenesmus, pruritus and spasm of the sphincter muscle of the anus, when provoked by congested hæmorrhoids. The systematic use of cold water directly after the daily evacuation, and again at bedtime should be the initial treatment. An enema of cold water should be used once or twice daily, if internal hæmorrhoids ex-

ist. These internal growths tend early to yield under this treatment unless they have attained to an excessive size, or have been strangulated by reason of frequent inflammations and systematic neglect. The neglected cases will, as a matter of course, require a longer continuance of the water treatment, but the number which in the end will demand surgical interference will be small.

UNCONTROLLABLE VOMITING OF PREGNANCY.

Drs. Henske (*St. Louis Clinique and Archives of Gynecology*, August, 1890) and Gottschalk have found menthol efficacious in stopping the uncontrollable vomiting of pregnancy. Fifteen grains are dissolved in five ounces of distilled water, to which five drachms of rectified spirit are added. A tablespoonful of this mixture is given hourly till the vomiting ceases. The editor of the *Archives of Gynecology* states that he has had an opportunity of trying the efficacy of this mixture. Vomiting ceased after the fourth tablespoonful. Dr. Gottschalk reports two cases with similar results.—*Brit. Med. Journal*.

DRY CUPPING FOR INFANTILE CONVULSIONS.

Dr. T. J. Heard says: In 19 cases out of 20, infantile spasms or convulsions may be arrested in one minute by the application of one or two dry cups on the back from the seventh cervical to the first dorsal vertebra. This will secure a remission, during which emetics, purgatives, or anything else that indications require, may be used.—*N. Y. Med. Times*.

THE ANTISEPTIC PROPERTIES OF CHLOROFORM.

Kirchner, in the *Zeitschrift für Hygiene*, writes that he has found that small quantities of chloroform act destructively and promptly upon the bacilli of cholera and typhoid fever. For this reason he would recommend that, during the epidemic prevalence of these diseases, this drug should be added to drinking water and milk, in the proportion of 1 or 2 per cent. He believes that this precautionary measure will be entirely free from danger as well as inexpensive. The addition of chloroform to lotions, used in surgical practice, would be useful, but more especially in mouth-washes and gargles, for the reason that the buccal cavities, even of healthy persons, often contain pathogenic microorganisms.

EPISTAXIS.

Dr. Jonathan Hutchinson recommends for the treatment of epistaxis the plunging of the feet and hands of the patient into water as hot as can be borne. He declares that the most rebellious cases have never resisted this mode of treatment.—*Boston Medical and Surgical Journal*.

SOCIETY PROCEEDINGS.

The Harlem Medical Association.

*Third Regular Meeting, Session 1890-91, held
Wednesday, Dec. 3, at 5 W. 125th street,
New York.*

E. FRIDENBURG, M.D., PRESIDENT, IN THE
CHAIR.

DR. E. L. COCKS presented a patient, S., male, 30 years, truck driver, whom he first saw May 11, 1889. Family history negative. Complained of numb feeling over right eye including the temporal and molar regions; also tingling sensations starting just in front of the right ear, running across the nose and including the right half of the upper lip. He did not feel the eyelid on winking nor a piece of cotton passed over the cornea. The eye protruded so that it was on a line with the nasal bone. He first noticed that the right eye was growing larger three months previous to his first visit. Could not close the lid over the right eye. On pressing over this eye backwards and slightly downwards a tumor as large as a hazel nut could be felt. It was immovable and quite hard. Its depth could not be determined. The cornea was clear but anæsthetic. The pupil was fully dilated but did not respond to light. Vision in right eye entirely absent. Left eye $\frac{2}{3}$. The ophthalmoscope showed the veins much enlarged but the arteries smaller. The optic nerve atrophied. He complained of nocturnal headaches. Six months previous to his first visit his hair commenced to fall out and he had sore throat. He denies all knowledge of syphilis, and claims never to have had an eruption of any kind. On examination, inguinal and cervical glands were enlarged and a syphilitic ulcer was found on the leg. The tibia is painful on pressure. No signs of initial lesion. Diagnosis, gumma of orbit pressing on optic nerve and vessels. Mixed treatment instituted, pushing the iodide in hopes of preventing a complete degeneration of the optic nerve. After three weeks of treatment headache better, appetite good, and he now feels the eyelid moving, also the cotton passed over the cornea. The vessels are now normal. The exophthalmia is much less. The tumor is sensibly melting away. By July 1 the eye resumed its normal position. There was a small ulcer of the cornea which disappeared under treatment with hot water and atropine. The sight has not returned. The nerve is in the same condition of atrophy as at the beginning of treatment. The patient does not know the exact period when his sight became lost in the right eye, but states his vision was good before the time when his hair began to fall out. His business did not require accurate vision; if it had he would have made the discov-

ery earlier. Had the patient been placed under proper treatment when the vision first began to fail it might have been restored. But, under the circumstances, the result of treatment is good.

DR. MAYER inquired if there were any evidences of syphilis in the throat; also, if the initial lesion had existed on the lip or tongue?

DR. E. L. COCKS replied there had been mucous patches in the mouth but no evidences of the initial lesion.

DR. R. VAN SANTVOORD stated that this case illustrated the fact, so often noted, that while the growths due to syphilis can be removed by proper treatment, the injury done to the nervous structures by these masses cannot be so easily remedied.

DR. G. H. COCKS thought the destruction of utility of the optic nerve was due to pressure. He spoke of two cases of gumma of the iris coming under his observation which yielded to treatment so far as the gumma was concerned, but the result was that the iris was immovable.

DR. E. FRIDENBERG called attention to the fact that the principle point of interest was that the gumma was located in the orbit as well as its large size. This condition is rare. That the cornea is now clear is a good result. Another interesting point is that the patient was not aware of his loss of vision. Frequently patients have imperfect vision, or perhaps no vision in one eye and are made aware of it only by some accident. A case came under his notice recently where the patient had been assaulted and the eye injured. He came to New York for expert examination before beginning a suit for damages for loss of sight. Examination proved that the lens was dislocated and there were other signs of long-standing lesions, certainly antedating the injury.

DR. C. B. MEDING suggested the possibility of a specific local neuritis independent of the pressure caused by the gumma. He believed it possible for the nerve to recover after the pressure, as all nerves are possessed of great vitality.

DR. E. L. COCKS thought it strange that one particular nerve should become the seat of neuritis while the other nerves of the orbit escaped.

DR. FRIDENBERG said the suggestion of Dr. Meding had engaged the attention of oculists, because it was well known that neuritis was often the result of small tumors in the brain. However, he did not think the case under consideration required that explanation.

DR. W. F. MARTIN presented photographs illustrating the following case: A boy, æt. 16, first came under treatment in June, 1890, suffering from alopecia areata over a considerable space. Galvanism was employed three times a week for six weeks with no improvement. Small fly blisters were then employed, three at a time,

to remove the epidermis. The electrodes were now dipped into a bichlor. sol. 1-3,000, and galvanism employed. From time to time the position of the blisters was changed, but were kept near the denuded area. After ten days a very fine growth of hair began to appear, but only where the blisters had been situated. This growth gradually became more marked and abundant. In three months the case was entirely cured. It is remarkable that in ordinary cases the hair begins to grow from the periphery, but in this case it began in the centre, which was probably due to the treatment.

DR. E. L. COCKS had seen a case in Dr. Buckley's clinic which had existed five months. The patient went to bed suffering from a headache, and, on rising in the morning found two bald spots on the scalp which were also anæsthetic. Carbolic washes had been used and the hair had appeared on one spot but not on the other.

DR. MEDING called attention to the fact that one theory of the cause of alopecia was that it was due to the accumulation of dandruff. It was commonly known that solutions of the bichloride of mercury were useful in this condition. Perhaps the solution had more to do with the cure of Dr. Martin's case than the galvanism.

DR. KNICKERBOCKER inquired of Dr. Martin how he explained the fact that the hair came back over the whole surface, whereas the bichloride solution had only been applied to limited areas?

DR. MARTIN had no explanation to offer, he only knew that the hair commenced to grow only on the surfaces denuded by the blisters and then gradually spread.

DR. G. H. COCKS presented to the Association a patient 26 years old, a fireman on the elevated railroad. On November 15 last, while at his work, he noticed a very peculiar numb feeling extending over the entire left side of his body. This feeling lasted only a very few minutes. One week later, while working on his engine, he felt a severe pain his left eye, as if a coal or spark had entered it. The muscles of the jaw became contracted and he fell forward unconscious on the boiler, receiving superficial burns on the wrists of both hands. The engineer did not notice any convulsions or frothing of the month. He was unconscious about half an hour. The important question is as to diagnosis, and, if these attacks are likely to recur. He is in line of promotion, but does not feel disposed to become an engineer if these attacks are to be repeated.

DR. VAN SANTVOORD was inclined to consider the case one of epilepsy having the usual aura and loss of consciousness. There may have been convulsive movements present although these were not recognized at the time.

DR. MAYER was inclined to leave the diagnosis open to see if there is a return of the attacks. In

the meantime he did not consider it proper for the patient to assume a perilous position.

DR. MALLESON inquired if the urine had been examined?

DR. COCKS replied that he regretted that he had not examined it. He had carefully examined the heart and found that normal.

DR. VAN SANTVOORD had a case of convulsions occurring in a woman suffering from albuminuria of pregnancy. The albumen was not found just before or after the attack. It appeared some twenty-four hours after the convulsive attack.

DR. FRIDENBERG believed it impossible to make a positive diagnosis in the case under consideration at the present time. We must wait until the case develops. It is possible for an attack of this character to be due to some peripheral irritation. He related the instance of his brother, a young man 23 years old, who had two attacks of loss of consciousness with some convulsive movements lasting a few minutes. Vomiting followed. These seizures were due to the eruption of a wisdom tooth.

Sulphichthyolic Acid and its Preparations in the Treatment of Inflammatory Diseases of Women—The Leprosy Commission in India—Spasmodic Dysmenorrhœa—Disinfection of Infected Premises—Miscellaneous Gleanings.

When ichthyol was first introduced into therapy it made a very considerable reputation, and was found by experiment to have a contractile influence upon the vascular system so that hyperæmia, inflammation and pain in any situation were relieved by its application. The disorders caused by or associated with dilation of the vascular system or anomalies of the circulation being so numerous, the remedy ran some risk of being regarded as put forward as a panacea. This was even more the case when the substance began to be used internally against organic affections or disordered functions, which could be regarded as due to or intimately connected with a dilated vascular condition. Quite a new direction for the display of the peculiar properties of sulphichthyolic acid and its preparations have been tried and it is now employed internally, not only in various skin affections, but also in the inflammatory diseases of women. Against these latter it is found to be generally more effective than any remedies previously in use. The results are found to be extraordinarily satisfactory as far as pain soothing and dispersing properties go. As regards methods of applica-

tion, that generally found sufficient externally was a 10 per cent. solution in glycerine, sometimes suppositories or ointment of ichthyol is also used. Internally the remedy is given in pills. Out of one hundred recent cases, thirty-four were completely cured, thirty-nine were considerably improved, and fifteen underwent a more or less pronounced change for the better. In only twelve out of the whole number was ichthyol without success. The remedy has been found to be convenient in application and favorable in action.

The members of the Leprosy Commission, consisting of Dr. G. A. Buckmaster, Radcliff Fellow of Magdalen College, Oxford, Dr. A. Kanthank, of St. Bartholomews Hospital, and Dr. B. N. Rake, Government Medical Officer of the Leper Asylum, Trinidad, have arrived in Bombay and will at once commence their work. The interest awakened in India by this commission is likely to extend to every place in the British possessions where this malady exists. The final report is to be subjected to a severe scientific analysis. The commission has been welcomed in India with every demonstration of approval and sympathy.

Dr. Champneys, in his lecture on Painful Menstruation, delivered before the Harveian Society, considered spasmodic dysmenorrhœa to be the only real dysmenorrhœa. The mechanical causes of the complaint he summarized under the heads of the theory of flexion, stenosis, and chronic congestion produced by flexion, but he thought this theory was inadequate. With regard to the question as to whether flexions were essentially associated with dysmenorrhœa, a large number of examinations made by observers in virgins, multiparæ and mothers, showed conclusively that ante flexion was not the usual cause of spasmodic dysmenorrhœa. As to treatment, he thought that division of the os led to an alleviation of the pain by setting at rest the irritated uterine fibres. Pregnancy, followed by parturition, appeared to be the physiological remedy. Hygienic measures, with plenty of Epsom salts, was the best prophylactic treatment. Division of the external os was always useless in such cases, but incision of the internal os, although it was a highly dangerous proceeding, was sometimes attended with good results, as was also dilatation of the cervix, when this operation was performed midway between the menstrual periods.

Among the most useful provisions of the Infectious Diseases (Prevention) Act of last session, are those relating to disinfection of infected premises. Hitherto the officers of sanitary bodies have been hampered in their endeavors to check the spread of infectious sickness among the poorer sections of the community by reason of the difficulties attending the adequate disinfection of living-rooms, it may be already over-crowded.

But power is now placed in the hands of all local sanitary bodies who choose to use it, of providing members of a family in which infectious disease has appeared, with temporary shelter or house accommodation, when they have been compelled to leave their dwelling for purposes of disinfection by the sanitary authority. Up to now such expenditure has not been a legal charge upon the district.

The refusal to admit women to medical examinations at Oxford gives just now somewhat increased interest to the signal success which the students of the London School of Medicine for Women have attained at the recent examination at the University of London. There were nine female candidates for the M.B. degree, and all have passed—five in the first and four in the second division; of the sixty male candidates fifty-two were successful. Among the medical schools University College and Guy's Hospital take the first place, each having eleven successful candidates. Next come St. Bartholomew's with ten, the London Hospital with seven, and King's College with six successful candidates. The total number of M.B. degrees granted by the London University this year is eighty, the largest number yet attained. Last year the number was sixty-four. The increase has been made notwithstanding complaints from some of the medical schools with respect to the severity of the requirements of the University. It is stated that the scheme of reconstitution, of which the Senate has resumed the consideration, does not progress very favorably, and gives no great promise of a satisfactory issue.

Mr. Lennox Browne has had under his charge a curious case, which must have troubled various physicians and surgeons. A middle-aged female patient was sent to him from the Provinces, and from her debilitated condition the supposition was that her malady was either phthisis or laryngeal cancer. The woman was tall and large boned, yet her weight was only 90 pounds. Mr. Browne ascertained that the real cause of her emaciation was the lodgement of a plate of artificial teeth, which had become firmly imbedded in the larynx, and had there remained twenty-two months. The patient remembered that one night she had been seized with a violent fit of coughing, and that her artificial teeth disappeared somehow during the paroxysms. Difficulty of breathing and pain in swallowing resulted from that very day. The obstacle having been dislodged, the patient has speedily recovered.

At the first meeting of the committee on hypnotism the following headings were decided upon as a basis for carrying out investigations: 1. The Nature of Hypnotism and its Nervous and Mental Relations. 2. Its General or Limited Applicability as a Therapeutic Agent in different classes of disease. 3. The Degree and Mode of

its Influence on Morbid Conditions. 4. Its Dangers and the Necessary Safeguards. Dr. Needham, the President of the Section of Psychology at the annual meeting of the Association in Birmingham, was unanimously elected Chairman of the Committee.

At one of the London Hospitals antiseptic sponges are prepared by plunging thoroughly clean and bleached sponges in a liquid composed of carbolic acid 10 grams, alcohol at 90° 20 grams, distilled water 100 grams, and essence of lavender 30 drops. After being left in this liquid for a few days they are washed with distilled water, which carries off the excess of carbolic acid. Very great antiseptic powers are claimed for the essence of lavender, which is not added merely for its agreeable odor.

Dr. Thorne Thorne will deliver the Milroy Lectures on Public Health at the Royal College of Physicians on February 17, 19, 24, and 26. The subject selected being Diphtheria, its Natural History and Prevention. G. O. M.

DOMESTIC CORRESPONDENCE.

LETTER FROM NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

New York Physicians and the Koch Lymph—Dr. J. H. Tyndale and the Treatment of Tuberculosis by Inoculation—Statistics of Phthisis and Pneumonia—Dr. Oliver Wendell Holmes on Academies—The State Commission on Lunacy—A History of Legislation for the Insane in the State of New York—Public Baths for Winter Use—Miscellaneous Gleanings.

During the past month quite a number of New York physicians, the most of them acting as representatives of medical schools and hospitals, have gone to Berlin to make a personal study of the inoculation method of Koch. The first consignments here of "lymph" from Germany were received about the same time at the Hospital for Ruptured and Crippled, St. Luke's Hospital and Mount Sinai Hospital, and the physicians of these institutions have been assiduously experimenting with it upon appropriate cases. At the first-named hospital the patients treated have been principally children suffering from spinal caries, hip-joint disease, and other similar affections.

In connection with the subject of the treatment of tuberculosis by inoculation, it may be of interest to mention that at the November meeting of the New York County Medical Association, Dr. J. H. Boldt called attention to the work in this direction which has been accomplished by one of the members of the Association, Dr. J. Hilgard Tyndale. For a number of years, he said, Dr. Tyndale has been pursuing experimental investi-

gations in the same line as Koch, and during the past year and a half he has met with excellent results from the inoculation of tuberculous patients with bovine virus diluted in a saline solution. Among the results noted have been the following: Cough diminished very rapidly, hectic disappeared, the bacilli decreased in the sputa, the weight increased and the general health improved. As in the case of Koch's inoculations, the constitutional symptoms immediately resulting from inoculation were quite severe. It is expected that Dr. Tyndale will present a detailed account of his experiments and their results to the Association at an early day.

In view of the special interest now attaching to the matter of consumption, Dr. John T. Nagle, of the Bureau of Vital Statistics of the Health Department, has prepared a table which shows the number of deaths from phthisis and from pneumonia occurring in this city during the last ten years; the deaths from both causes being given for the reason that cases of phthisis sometimes terminate in pneumonia, and many cases of pneumonia are of a chronic character, although this is not always stated in the death certificates. This table is as follows:

	Deaths from Phthisis.	Deaths from Pneumonia.	Deaths from all Causes.
1880	4,706	2,822	31,937
1881	5,312	3,261	38,624
1882	5,247	3,472	37,921
1883	5,290	3,409	34,011
1884	5,235	3,159	35,034
1885	5,196	3,649	35,682
1886	5,477	3,657	37,351
1887	5,260	3,707	39,933
1888	5,260	4,288	40,173
1889	5,179	4,075	39,697
Total	52,162	35,499	369,350

The table shows that the percentage of the deaths from phthisis to the total deaths in the city in these ten years was 14.12.

There can be no question that the most attractive feature of the ceremonies recently held at the formal opening of the new building of the Academy, was the reading of the characteristic and noble letter sent by Dr. Oliver Wendell Holmes, of Boston, who was unable to be present in person on this occasion. It was, in part, as follows: "Academies have been too often thought of as places of honorable retirement and dignified ease—roosts where emeritus professors and effete men of letters, once cocks of the walk, could sit in quiet rows, while the fighting, the clucking and the crowing were going on beneath them. . . . But the academy which fulfils its true functions is a working body. It deals with living subjects; it handles unsettled questions; it sets tasks for its members and furnishes, so far as it can, the appliances for their prosecution; it offers rewards for meritorious performances and sits in judgment on the efforts of aspirants for distinction. It fur-

nishes the nearest approach we can expect to a fixed standard of excellence by which the work of new hands and the new work of old hands can be judged. It is a barrier, a breakwater, against the rush of false pretensions which are constantly attempting to find their way into public confidence.

"Nowhere is such a defense more needed than in the sciences and arts which deal with the health of the community. The public is so ready, so eager to be deceived, and the traders in deception are so willing, so hungry to deceive those who will listen to them, that it needs a solid wall of resistance, a close, united phalanx of men of recognized sense, knowledge and character to stand against them. The various forms of what I will venture to christen as pseudo-pathy and pseudo-therapy—though they are known to the public by other names—can never loosen the intelligent, thoroughbred physician, or the enlightened members of society, so long as the best heads of the profession are banded together in a noble institution like this Academy. We look to this great and able body of men to guard the sacred avenues to the temple of science against all worshippers of idols. The medical profession will always have to fight against the claims of wrong-headed and too often dishonest individuals, and 'schools,' as they call themselves. A portion of every community will always run after the false prophets. There are a certain number of squinting brains, as there are of squinting eyes, among every thousand of our population. There will always be a corresponding number of persons calling themselves physicians ready to make a living out of them. Long may it be before the wholesome barriers are weakened that separate the thoroughbred and truly scientific practitioner from the plausible pretender with his pseudo-pathy and his pseudo-therapy."

It would certainly seem to be well that some of our New Code friends among the officials as well as Fellows of the Academy, who have done all in their power to break down these "wholesome barriers," should ponder deeply these wise counsels of the genial and venerable Autocrat.

The State Commission in Lunacy has adopted two orders which it is believed will be of considerable benefit to the welfare of the patients in the State hospitals for the insane. The first provides that each insane patient shall be permitted to write to some friend or relative at least every two weeks, and, in the case of patients unable for any reason to write, the medical superintendent of the hospital must direct some proper person to write for such patients at suitable intervals, if they so desire. All letters of insane patients which are detained must be forwarded to the Commission, accompanied by a statement of the reasons for such detention; and all letters addressed to State officers, judges of courts of record, and district attorneys, must be immediately forwarded without examination.

The second order states that, in view of a custom which has long prevailed of permitting patients to temporarily leave institutions for the insane to visit friends, or to go out "on trial" for an indefinite period, and it also having been made to appear that due diligence has not always been exercised to ascertain the whereabouts of insane patients who have escaped, and to promptly secure their return, and as in cases where long intervals elapse between the date of parole or escape and the return of patients to an institution, the possibility may arise of their being reconfinement when not insane by reason of their recovery during such interval, it is ordered that no insane patient, while in the custody of an institution, be permitted to go upon parole who, in the judgment of the medical superintendent, is dangerous, either to himself or others; that no parole be granted for a longer period than thirty days; that upon the escape of a patient prompt and vigorous measures be taken to secure his return; that a patient who has been paroled or who has escaped, if not returned to the institution by the thirtieth day thereafter, must be discharged from the books of the institution upon that day, and a notice of such discharge must be forwarded to the Commission; and that such patient must not be readmitted except upon a new medical certificate of lunacy, the cost of which (except in the case of a private institution, by special agreement), must be borne by the institution.

In view of efforts which are now being made by certain interested parties to bring to bear such influence upon the State Legislature as will render null and void, as far as possible, the beneficent provisions of the act establishing State care for the insane poor passed at its last session, an able writer in *Utica* has prepared an interesting history of legislation for the insane in this State, and the opposition which the friends of reform have had to encounter during the last quarter of a century. From this it appears that twenty-five years ago the Legislature passed an act little less than revolutionary as far as the preconceived ideas of many were concerned, which had for its object the freeing of the insane poor from the thralldom of the brutal and ignorant keepers of the county almshouses. The passage of this act was the culmination of a fierce struggle between the friends of humanity and intelligence on the one side, and those of ignorance, viciousness and cupidity on the other.

It is worthy of note, however, that the measure was opposed by one man of great eminence as an alienist, who for many years was Superintendent of the State Asylum at *Utica*, and who received the high honor of being made the second President of the New York State Medical Association, the late Dr. John P. Gray. He did so not because he was hostile to a higher ideal of treatment for the insane poor, but because he contended that

the act was based upon a wrong theory, for the reason that it confirmed a policy of the State which he regarded as highly detrimental, namely: that which declared that after a certain length of time or under certain circumstances insanity was incurable, and provided that the insane poor, after a short period of treatment—usually less than two years—might be sent to the asylum proposed to be established under the act and cared for as "chronic insane." Dr. Gray did not live along to see the Legislature of the State come to his way of thinking; but it is gratifying to those who hold his memory dear that this brilliant, accomplished and humane man was nearly twenty-five years in advance of his contemporaries on a question involving such profound human sympathies.

This act provided for the establishment of a State Asylum for the Chronic Insane, and that all of the so called chronic insane in the poorhouses at that time should be transferred to it as soon as the buildings were completed; but the men who profited by the care of these individuals soon showed that they were not to be so easily deprived of their spoils. With great cunning they changed their tactics, and under the guise of patriotism and unselfish desire to relieve the taxpayer, they defeated from year to year the passage of appropriations for the enlargement of the Willard Asylum for Chronic Insane. After a few years of such tactics they came before the Legislature with statements like the following: "Now, you see that this asylum will not be enlarged rapidly enough to accommodate all the insane as fast as they ought to be provided for. We propose that you give these county people another chance. They mean well. These insane poor live in their midst, and they are tenderly attached to them. They desire that their friends shall have the opportunity of frequently visiting them, and it is wicked to remove them farther from their homes. Now, why not provide a scheme whereby certain of the 'good' counties can be exempted from the operation of this statute so long as they care for these poor people properly? You can at least try them, and if you find that they are not honorably living up to their promises, then the exemptions can be revoked. This plan will relieve the State and at the same time will satisfy the counties."

This sophistry prevailed, and the proposed plan was carried out. Much that had been gained was lost. The principle ostensibly contended for was practically abrogated, and the old abuses of the system of county care were rapidly revived. The exemptions continued to be granted until twenty counties were relieved from the necessity of sending their chronic insane to the Willard State Asylum; and for many years the evils attendant upon the confinement of insane patients in local poorhouses, with utterly inadequate medical care, continued unabated. About four years ago, however, the State Charities Aid Society turned its

attention to the condition of the insane in the county almshouses and in the so-called county asylums of the State, and the result of its investigations was to instigate prompt measures for the remedying of this great abuse once more. With this end in view legislative action was sought, and the heroic efforts of this philanthropic organization, backed by the press and by numerous medical societies, as well as the great mass of the medical profession, are now well known. Each winter up to 1890 these efforts were defeated by a most vicious combination of meanness, greed and petty politics; but in 1889 the Society came nearly to the point of success, its bill providing for State care of the insane poor being defeated by only a few votes.

At this juncture another potent factor was brought forward, namely: the State Commission in Lunacy, a central board endowed with ample powers, which was created in 1889, after a ten years' struggle in the Legislature by the advocates of such a commission. The first report of the Commission, with Dr. Carlos F. MacDonald, a physician with twenty years' asylum experience, at its head, fully confirmed all that the State Charities Aid Society had previously reported in regard to the disgraceful condition of the insane poor in the various county institutions; and it was no doubt largely due to this that the act now in force was passed last winter. This act, it will be remembered, provides for the care in State Hospitals of all the insane poor, including both acute and chronic cases, in the State, with the exception of New York, Kings and Monroe Counties. For the first time in the history of the State it is legally recognized that the insane are wards of the State; and the act also recognizes the principle that insanity is a disease, and as such is amenable to treatment like other diseases.

As in 1865, so in 1890, the friends of the county poorhouses and asylums, with a brazen effrontery, are at work to undo as far as possible the good that has been accomplished; but they are not very consistent in their talk. They insist that they want to do nothing more than care for what they are pleased to term the chronic or incurable insane, and yet in the same breath they state—an assertion not very creditable to their vaunted intelligence—that they cure more of these in their local institutions, and it must be remembered, without any appliances or any medical skill worthy the name, than the State hospitals provided with all the most approved modern facilities for the treatment of the insane. Their plan of campaign is being rapidly arranged. Thus, the Board of Supervisors of one of the counties in the central part of the State at a recent session issued a circular calling upon the similar boards of other counties to aid them in the movement, and to ask for the repeal, and failing in that, the modification of the new law

establishing State care for the insane poor. By the term modification it is not clearly shown what is meant, but it is intimated that the old tactics of 1865 are to be again employed, and that an effort is to be made to exempt certain of the "good" counties from the operation of the statute, and, if this should fail, to defeat all appropriations for carrying out its provisions. It is a fact that the county authorities, now that this act has been passed, decline to take any steps whatever towards bettering the condition of the insane poor still remaining under their charge. Now they propose to prevent the appropriation of money for their removal, and if they are successful the result can only be that the condition of these people, bad as it is now, will grow worse.

A curious feature of this movement is that the whole contention is over only about one-fourth of the insane poor of the counties of the State exclusive of New York, Kings and Monroe Counties. In the other fifty-seven counties, there are, according to the report of the Commission in Lunacy, considerably less than eight thousand people of this class. Over five thousand of these patients are now provided for in the State hospitals, so that the effort is directed to preventing less than one-fourth receiving the same care and treatment as the other three-fourths; the ostensible pretext for this being that the one-fourth are incurable insane, have been declared so by statute, by lapse of time, and by the opinions of the superintendents! By the 1st of October, 1891, with the appropriations which have already been made by the legislature, it is estimated that the number of insane poor still left unprovided for in the State hospitals will not exceed 1,200.

The subject of public baths, for winter as well as summer use, is just now receiving considerable attention, especially in view of the fact that many of the city's free summer baths along the Hudson and East Rivers are adjacent to the mouths of sewers and in consequence endanger, to a greater or less extent, the health of the bathers. At a recent meeting of the Section on Hygiene, Public Health and State Medicine, of the New York Academy of Medicine, Dr. Simon Baruch, who has given much attention the subject, read a paper entitled "A Study of the Public Baths, together with an Inexpensive Method for their Hygienic Utilization," and in it he proposed a plan for the establishment of public shower baths, such as are now in use in Berlin and Vienna. Acting on the suggestions of Dr. Baruch, the Society for Improving the Condition of the Poor have determined to erect on a site in the midst of a down-town crowded tenement district which has been offered them by the City Mission and Tract Society, a two-story building, 27x61 feet, in which it is proposed to have a reading-room with an open fire-place and twenty-

four large apartments for bathers. Only shower or spray baths will be provided, these being believed to be the most efficient for the preservation of health; and each apartment is to have a subdivision to be used as a dressing room. Tickets entitling the holder to a bath and the use of soap and towels, will be sold for five cents to those able to pay for them, and given free to others, and hot coffee will be given to those who desire it on leaving the bath during the winter months. It is estimated that one thousand persons can bathe each day, and on three days of the week the building will be reserved exclusively for females.

Football has never been so strongly and so brilliantly played in this country as in the great games between Harvard and Yale, and Yale and Princeton during the past month; and, better than this, these games have satisfactorily proved that football can be a gentlemanly game and not the brutal exhibition of prize-ring methods that have so often disgraced it in the past. It is well that the game has achieved that character with the general technical improvement that is manifested in the way in which it is played; and, in fact, football has now taken a place in the front ranks of athletic sports, both as regards the character of the young men who engage in it, the perfection of skill displayed in the playing, and the popular interest manifested in it.

The women of New York are determined not to let their London sisters surpass them in zeal for the support of the hospitals, and while they may perhaps never adopt the plan of street collections so popular in that city, where even ladies of the highest social position do no think it beneath their dignity to charge themselves with the care of a sidewalk collection stand on "Hospital Day," they have this year organized a Women's Auxiliary of the Hospital Saturday and Sunday Association by means of which they hope to materially increase the amount of the annual public collection for the hospitals. Their special object is to carry out the work of the charity more thoroughly than ever before in all branches of the retail trade, and for this purpose eighteen different committees of ladies have been appointed.

A young man recently arrested here on the charge of theft adopted a very clever ruse for making his escape. On arriving at the station house he stated that he had taken a large dose of laudanum, and under the circumstances an ambulance call was sent out. The ambulance surgeon, on his arrival, thought it would be advisable to make use of the stomach-pump, and on asking for some hot water, the two officers in charge of the prisoner left him to get it from the stove. No sooner were their backs turned, however, than the agile prisoner dashed out through

the back door, which chanced to be open, and before the astonished officers had recovered their senses he had climbed over the wall of the yard and made good his escape.

Columbia, Tenn., January 5, 1891.

ASSOCIATION NEWS.

PERMANENT MEMBERS.—From the list of Permanent Members of the Association published in THE JOURNAL for December 27, 1890, the following names were unintentionally omitted:

Cannaday, C. G., Roanoke City, Va., 1890.
Duffield, George, Detroit, Mich., —
Way, Eugene, Dennisville, N. J., 1889.
Woodruff, L., Alton, O., 1883.

In revising and copying so many names by the Secretary and Treasurer, there may have occurred other omissions; if so, we will supply the defect by publishing all additional names to which our attention may be called.

MISCELLANY.

LETTERS RECEIVED.

Dr. Joseph Smith, San Jose, Cal.; Dr. Paul Paquin, Columbia, Mo.; Damrell & Upham, Doliber-Goodale Co., Codman & Shurtleff, S. R. Niles, Boston, Mass.; Dr. C. D. Watson, Ontario, Cal.; Dr. W. A. Scott, Swanton, O.; Roberts and Allison, Indianapolis, Ind.; Dr. F. E. Udell, Katharmon Chemical Co., St. Louis, Mo.; Mutual Library Co., Bellevue Hospital Medical College, C. L. Topliff, Thos. Leeming & Co., Jas. F. Madden, J. H. Bates, G. E. Stechert, New York City; Dr. D. S. Lamb, Dr. C. R. Greenleaf, Dr. Irving C. Rosse, Washington, D. C.; Dr. Wm. B. Hill & Co., Meyrowitz Bros., T. C. Morgan & Co.

Official List of Changes in the Stations and Duties of Officers Serving in the Medical Department, U. S. Army, from December 27, 1890, to January 2, 1891.

Capt. William J. Wakeman, Asst. Surgeon, is relieved from the further operation of par. 13, S. O. 254, A. G. O., October 30, 1890, and telegraphic instructions of the 16th inst., from this office, transferring him from Ft. Bidwell, Cal., to Ft. Huachuca, Ariz. Ter., and he will return from Reno, Nevada, to Ft. Bidwell, for further duty at the latter post. By direction of the Secretary of War. Par. 3, S. O. 300, A. G. O., December 24, 1890.

First Lieut. Ogden Rafferty, Asst. Surgeon, is relieved from duty at Ft. Sam Houston, Tex., and will report in person to the com'dg officer, Camp Eagle Pass, Tex., for duty at that station, reporting by letter to the commanding General, Dept. of Texas. By direction of the Secretary of War. Par. 2, S. O. 301, A. G. O., December 26, 1890.

Major Stevens G. Cowdrey, Surgeon, extension of leave of absence on account of sickness granted in S. O. 293, December 16, 1890, from this office, is still further extended one month on account of sickness. By direction of the Secretary of War. Par. 8, S. O. 302, A. G. O., Washington, December 27, 1890.

Major John S. Lauderdale, Surgeon, now on duty at Ft. Ontario, N. Y., will proceed to Pine Ridge Agency, S. Dak., without delay, and report in person to Brig. Gen. John Brooke, for duty in the field, and by letter to the commanding General, Dept. of Dakota. By direction of the Secretary of War. Par. 8, S. O. 303, A. G. O., Washington, December 29, 1890.

Official List of Changes in the Medical Corps of the U. S. Navy for the Week Ending January 3, 1891.

Asst. Surgeon G. McC. Pickrell, detached from U. S. R. S. "Minnesota" and wait orders.

Asst. Surgeon A. M. D. McCormick, ordered to the U. S. R. S. "Minnesota" as Dr. Pickrell's relief.

ADDRESSES.

SANITATION IN 1890.

*The President's Address to the American Public Health Association,
at its Eighteenth Annual Meeting, Charleston, S. C.,
Dec. 15, 1890.*

BY HENRY B. BAKER, A.M., M.D.,
OF LANSING, MICH.

Members of the Association, Ladies and Gentlemen:

In accordance with the custom in this Association, this address is now presented in order to supply a general view of the present status of public-health work in this country, to bring briefly before us a review of some of the progress made, especially since the last meeting of this Association, and to suggest directions in which effort seems to be needed in order that progress shall be most satisfactory and promising for the future.

Many of you are as familiar as I am with these several topics, but as each member of our Association views them from a different standpoint, there is reason for a hope that what is presented in this address may not be tiresome, and I do not forget that there are some present to whom public health topics must be new. To such persons I may say that, although many of its members are physicians, this Association is not a medical association; although many of its members are especially well informed on subjects relating to personal hygiene, yet personal hygiene is not the subject which is uppermost in the minds of members of this Association. If you ask what, then, are the objects of this Association, the reply is found in its name,—“The American Public Health Association,”—and in its constitution wherein it is stated: “The objects of this Association shall be the advancement of sanitary science, and the promotion of organizations and measures for the practical application of public hygiene.”

The founders of this Association recognized the fact that in civilized society the life and health of every person is more or less bound up with the life and health of every other person, that not only is man his “brother’s keeper,” but on each person there rests some responsibility

for the welfare of all,—some responsibility for the public health; and each person has a vital interest in the public health, because of its bearing upon self-preservation.

We have all heard that “self-preservation is the first law of nature;” but I think we must admit that it is not the first, but more frequently the last law of the law-maker. Laws for the preservation of human life and health, in accordance with sanitary science, are of slow growth, and an important object of this Association is “the promotion of organizations” “for the practical application” of sanitary science for the public good, and such organizations for the public good can, as a rule, best exist only through public law, and the ordinary governmental methods.

Governmental methods differ somewhat in the different parts of America, and we must remember that this Association includes representatives not only from the several States of this Union, but also from the Provinces and the Dominion of Canada, and I am happy to say that this year marks a new epoch, for we have with us officially appointed representatives from the general government of Mexico, eminent members of its Superior Council of Health.

If, then, this address is to deal with those objects for which this Association was organized, it must deal with the advancement of sanitary science, and the promotion of sanitary organizations; and, in the United States, the most perfect “organizations” for the practical application of measures for the public good must conform to our form of government, “of the people, for the people, by the people.” In my opinion, there should be such a sanitary organization for the United States and for each other general government, for each of the several States and Provinces, and for each of the numerous local governments.

Advancement of Science. The Causation of Diseases.—It seems evident that no great and substantial progress can be made toward the prevention or avoidance of a disease until we have knowledge of its causation. Therefore the work which it is most important shall be first accomplished is that which shall yield us knowledge of the causation of each disease. Within recent years much progress has been made in this important fundamental knowledge, thanks especially to two en-

lightened governments—Germany and Great Britain.

It should be clearly held in mind that there are seldom less than three important factors, neither of which can be neglected in studying the causation of a disease. For instance, there is (1) the "specific" cause, (2) what (when dealing with atmospheric conditions) I have called the "controlling" cause, and (3) the "predisposing" cause.

Causation of Consumption.—By all means the most important addition to our knowledge in this field, is that for which we are chiefly indebted to Dr. Robert Koch, of the Imperial Board of Health of Germany,—the definite knowledge of the tubercle bacillus—the "specific" cause of consumption, the disease which causes the greatest mortality, in this country, and throughout the world.

Every year there is being rapidly added to our knowledge, details of the controlling conditions, predisposing causes, and modes of spread of that most important disease—knowledge which will enable us to explain the methods by which this most dread disease may be prevented.

Causation of Pneumonia.—The necessity for further knowledge of the causation of a disease than is supplied by knowledge of its "specific" cause is exemplified in the case of pneumonia, which disease, it is believed, can be artificially produced in lower animals by means of its specific cause,¹ yet the causation of which in man and in animals is certainly proved (by statistics and by direct experiments) to be controlled, in great part, by conditions of the atmosphere.²

One attempt to harmonize the facts from these two very different sources, is that by Dr. William B. Canfield, who says: "In the light of recent studies made by Metschnikoff,³ Baumgarten,⁴ Osler⁵ and others, it is more than probable that the phagocytes in a healthy individual, having healthy movements, are able to seize and assimilate the invading organisms, and it is only when an individual not well when the phagocytes lose the power to battle against the specific organism of pneumonia from prolonged exposure to cold, that pneumonia sets in."⁶

But experiments more recent than those referred to by Dr. Canfield, by Nuttall, Buchner, Nissen, Lubarsch, Prudden and others, indicate

that the blood serum, even more than the leucocytes, is concerned in the destruction of pathogenic microorganisms.⁷

Causation of Diphtheria.—Evidence has been accumulating, and it now seems to be established that the bacillus discovered by Loeffler is a specific cause of diphtheria. Dr. Klein, F.R.S., London, has demonstrated that in the cow inoculated with diphtheria, the bacillus passes into the milk. This may account for the spread of diphtheria in some cases, otherwise unaccountable. In the trachea of cats the bacillus is alleged to have caused pneumonia,⁸ which was, I suppose, diphtheritic. Some experiments with doves by Babes and Piscariu⁹ seem to have been especially well planned, and to have yielded results especially important. They found that the bacillus—the specific "germ"—promptly caused diphtheria in doves whose throats were scarified before the application of the bacilli, but did not cause the disease in doves with perfectly healthy throats. That something analogous to this is true, as a rule, concerning diphtheria in man, was claimed to have been indicated by myself some years ago, especially in my paper on the "Causation of the Cold Weather Diseases."¹⁰ The hypothesis which I then published I still believe to be the true explanation, as to the way in which the throat is irritated and made sore, and consequently susceptible to diphtheria and other diseases, by exposure to the inhalation of air unusually cold and dry. But Dr. K. E. Wagner (*Annales de l'Institut Pasteur*, p. 570, No. 9, t. 4, Sept. 25, 1890) has repeated Pasteur's experiments, producing anthrax in fowls by lowering their temperature by cold water, and has found that it can be done if the lowering is by means of antipyrin. His experiments indicate that when the temperature is lowered the rate of destruction is less than the rate of reproduction of the anthrax bacilli, while at the normal temperature of fowls, and especially when raised by the injection of the bacilli, the rate of destruction of the bacilli is greater than their reproduction, in the bodies of fowls, especially in the blood. Outside the body at such temperature (42° C. to 43° C.) the anthrax bacilli do not form spores, and are killed in nine days.¹¹

Experiments are needed to prove whether what is true of anthrax is also true of the other diseases which I have shown to be most prevalent after the cold weather.¹²

Whether or not my hypothesis shall be found to be the correct explanation relative to the en-

trance of diphtheria, experiments indicate that it is true, in part at least, relative to pneumonia,¹³ and the fact now seems to be established that diphtheria, small-pox, pneumonia, and some other diseases that usually enter the body by way of the throat or air passages are increased in prevalence at such times as people are exposed to cold atmosphere.

Quarantine.—It is significant of great progress, I think, that the diseases which it now seems most important to dwell upon, are not the same as in former times. Comparatively little is now said of small-pox, cholera, or yellow fever. In this country these diseases are not such important causes of death as consumption, diphtheria or scarlet fever. For this result, general progress in sanitary administration must receive much credit; but I think that, in this country, much credit must also be due to the greatly increased efficiency of the quarantine services, notably at such important ports as New Orleans, Quebec, and New York. Here, in Charleston, the efficiency has been greatly increased.

The United States Government, also, has, in recent years, done very much more than ever before for the establishment, equipment and maintenance of quarantine stations.

A continuance of this work is desirable; but, for substantial progress, something more than merely continuing the present methods of quarantine is needed. Diphtheria and scarlet fever should be excluded by quarantines; but the entire country is permeated with those diseases, and with the still more important one—consumption; and a *Health Department of the Interior* is needed to be established at Washington, even more than is a continuance of quarantine.

Cholera.—To be forewarned *should* be to be forearmed; but our long continued immunity from cholera in this country has led to a general belief that there is no longer danger from cholera in the United States,—a belief which may be true, but, in my opinion, is not fully supported by facts. The constant presence, throughout the United States, of typhoid fever,—a disease which is believed to be spread in almost the same ways in which cholera is spread, should, it seems to me, teach us more humility as to the assumed sanitary superiority of our people and their surroundings, and should lead us to urge the people to adopt those measures which are now known to be restrictive and preventive of both cholera and typhoid fever.

It should not be forgotten that our greatly improved systems of quarantine at our leading seaports do not yet ensure us against the introduction of cholera in the same manner in which it

was introduced in 1873 when three distinct outbreaks of cholera, in widely remote parts of the United States, were traced to the unpacking of personal effects of immigrants,—at Carthage, Ohio; Crow River, Minnesota, and Yankton, Dakota. So long as conditions are permitted to remain which result in the annual spread of typhoid fever in every State of this Union, there is good reason to believe that cholera would spread, if introduced at a season of the year favorable thereto.

It should be, but is not, generally understood that there is coming to be a thickly-populated area in a portion of this country in which by reason of alkaline waters the inhabitants are probably especially liable to typhoid fever, cholera, or other diseases propagated by microorganisms which enter the body by way of the alimentary canal, and which microorganisms are generally destroyed by the normal acid of the healthy human stomach.¹⁴ It is not probable, but it is possible that if cholera should become once thoroughly established in the warmest portion of the region of alkaline waters in this country, it might possibly find there a permanent home, as it has in the brackish waters of the Ganges in India.

The bare possibility of such a calamity as the permanent addition of cholera to the diseases constantly present in this country should prompt the United States government to a thorough investigation of the subject, lest, through careless disregard of such duties by the government, the lives of thousands, perhaps millions of our people should be jeopardized.

Typhoid Fever.—But, after all, is cholera a more fatal disease or one more to be dreaded than its twin destroyer—typhoid fever? The number of deaths from typhoid fever reported as having occurred in the United States during the census year 1880, was 22,854;¹⁵ and it is probable that not much more than half of the deaths were reported, because the method of collecting the statistics of death for the U. S. Census is known to be very defective. We are apt to look with contempt upon the East Indians for living under conditions which permit their destruction by cholera; while at the same time our own people are permitted to be swept off by the thousands in every year by a disease which we believe to be propagated in almost precisely the same manner that cholera is, and our National Government is doing absolutely nothing to prevent its continuance—does not even grant to its National Board of Health a dollar to investigate and report on the best methods for the prevention of this great waste of life and treasure that continues to go on notwithstanding the belief of leading sanitarians that in great part it is unnecessary, and might easily be prevented without the use of more money

¹³ Dr. Vito Platania, in Italy—*Giornale intern. delle scienze mediche*, fascicule v.; also *Bulletin Général de Thérapeutique*, Paris, Dec. 15, 1889, p. 527; also *Boston Med. and Surg. Jour.*, Jan. 23, 1890; also *Therapeutic Gazette*, Vol. xiv. No. 2, Feb. 15, 1890, p. 142.

than is annually wasted through preventable sickness from this disease.

I think it is important that the Government should investigate the reason for the prevalence of typhoid fever, "mountain fever," etc., in the region of the Rocky Mountains, and especially in the region of alkaline waters. Such an investigation might throw much light upon the subject of the causation and better means of prevention of fevers throughout the entire country.

Causation of Yellow Fever.—Are not all the facts known relative to yellow fever, compatible with the belief that the disease is caused by the inhalation (or otherwise taking into the human body) of the products of the growth, reproduction, or life processes of some organism, probably microscopic in size, which organism may not be capable of reproduction within the human body, but is capable of reproduction in filth outside the body, at high temperatures, but which organism is destroyed by a freezing temperature?

If there is such compatibility in the facts, is it not desirable that the United States Government should take such measures as shall ensure the thorough searching for such hypothetical microorganism, not in the bodies of yellow fever patients, but in localities known to be infected?

Is not the importance of this subject, either as affecting the lives of citizens of this country, or as affecting the money interests of our people, sufficient to warrant the employment of a number of investigators, and the expenditure of considerable sums of money for investigations in the directions indicated by the facts in the possession of physicians and sanitarians?

It has been found that without the presence of oxygen (as in the human body) the cholera bacteria produce their poison more energetically and more quickly than in the presence of air; but when developed in the absence of oxygen the cholera bacteria are much more sensitive, traces of acid being sufficient to destroy them. When they first leave the body they are, therefore, easily destroyed by the gastric juice in the healthy human stomach, and cannot reach their habitat in the intestine, but if developed outside the body, in the presence of air, the bacteria soon become aerobic and not so easily destroyed. This seems to explain why cholera (like typhoid fever and yellow fever) is only seldom directly contagious, and why the disease is contracted in an infected locality.¹⁶ Something similar or analogous to this being true in typhoid fever, and a noticeable fact in yellow fever, the facts respecting the cholera bacteria may aid in the search for the specific cause of yellow fever.

A Possibility of the Prevention of Cancer.—A study of the locations of 7,881 primary carcinomata,¹⁷ as illustrating the probability of a cancer-

ous microbe, has led Dr. Edmund Andrews, of Chicago, Ill., to believe that the facts he has collected and presented make it probable that a microbe exists, and prove the importance of searching out the microbe; also that much can probably now be done towards preventing this disease, by measures looking to the prevention of access of microbes to those parts of the body most susceptible to primary cancer, especially the lower lip, its liability to primary cancer being "8,448 times greater than a similar area of the intestine."¹⁸

In this connection may be held in mind, an epidemic or outbreak of cancer attributed to the use of cider in the making of which water from an impure source was used.¹⁹

Inflammation.—A proposed general advance "all along the line."—It is coming to be the general belief of physicians, and especially of surgeons, that nearly all inflammations are caused by the presence of microorganisms. (Some of the most common of these pus generators are the round ones—the micrococci, sometimes grouped by twos, and in chains, etc.—*staphylococci*, and *streptococci pyogenes*, three varieties of each: the *albus*, *aureus* and *citreus*.)

Some of these microorganisms are now very widely and generally distributed in thickly inhabited places, while in sparsely inhabited regions, especially in mountainous regions, they are not so generally found. I think we should put with this fact another one—that most new States and localities are, apparently, good health resorts. I remember well that, many years ago, certain States in this Union were considered exceptionally healthful as regards diseases of the lungs, while now the mortality statistics in those States show the greatest proportion of the deaths to be from diseases of the lungs. Part of this change may be due to a change in the average age of the inhabitants, but I think a part of it is due to the fact that the microscopic causes of inflammation have constantly been increasing, so that now the carpets and upholstered furniture in most residences, the floors of most public assembly rooms, the clothing, hair, beard and hands of most of the inhabitants, are infected with these microscopic causes of inflammation.

quent on those surfaces which, by their position, would be most accessible to free-swimming microbes or spores derived from without the body.

2. The liability to cancer is increased if the epithelial surface is so situated that the spores can remain upon it for at least some hours without being swept away, as on the lower lip; but the liability is greatly diminished if the parts are frequently swept off, as the globe of the eye by winking, or the esophagus by swallowing food and drink.

3. The liability to cancer is great if the membrane has vast numbers of deep glandular follicles, into which the spores can penetrate and lie free from disturbance, and have direct access to the more delicate epithelial cells, as at the pyloric end of the stomach and the follicles of the mammary glands.

4. Those portions of the skin which are usually uncovered are oftener attacked than those covered with clothing and constantly brushed by its friction. The skin of the face, for instance, produces more cancers than all the covered portions of the integument combined.²⁰—JOUR. OF THE AMER. MED. ASSOC., November 23, 1889, p. 739.

¹⁶ Amer. Jour. Med. Sci., July, 1890, p. 77.

¹⁷ Other things being equal, primary carcinoma is most fre-

The surgeons have been acting upon this comparatively recent addition to our knowledge, and to those of us who practiced surgery only as long ago as during the late war, the successes in recent surgery are marvelous. Not long since, I listened to the recital of the details of fifty-two successive surgical operations, each involving the opening into the abdominal cavity, and each was successful. (Trans. Mich. Med. Soc., 1890, p. 349.) My belief is that much of such wonderful success as is now achieved by the leaders in surgery is due to the advance of our knowledge upon what was formerly known as "the germ theory of disease," which gave rise to what was known as "antiseptic surgery," which is now giving place to what is known as "aseptic surgery." The septic microorganisms are now kept out of wounds, pus does not form, inflammation does not occur, the wounds heal, and the patient recovers.

What I am about to propose may seem to some of you at first as Utopian, but I hope to be able to enlist your enlightened sympathies in the direction of a movement designed to do away with all inflammatory diseases of man, in a manner analogous to what has been done by the leading surgeons in doing away with inflammations following surgical operations. Let us glance at the stupendous character of the suggestion—to gradually but eventually do away with all inflammatory diseases! No more consumption, pneumonia, bronchitis, laryngitis, pharyngitis, tonsillitis, rheumatism, etc., including nearly all the dangerous communicable diseases.

So far as relates to the dangerous communicable diseases, such as small-pox, scarlet fever and diphtheria, sanitarians now know how to restrict, and perhaps to stamp out most of them, and they are doing this as fast as they are supported in doing it by Governments, but the measures I have to suggest would, I think, tend to aid greatly in that work, and, in addition, would aim to place at once all inflammatory diseases on the list of preventable diseases—diseases which we think we know how to prevent just as soon as the people generally shall come to understand the methods proposed, and shall generally coöperate in the employment of those methods.

Without elaboration,²⁰ my proposition may be put in the form of preamble and questions, thus:

Since nearly all suppurative inflammations are breeding-places for microorganisms which, when they gain entrance into another living body (or into another weak or injured spot in the same body), are capable of again starting the inflammatory process, therefore,

Should not all purulent discharges, and all pus which is accessible, be destroyed or disinfected?
Should not the aim be thus to restrict the spread,

²⁰ I hold clearly in mind methods which if adopted, would, I think, probably be effective, but the statement of them cannot be attempted here. Among the most important measures would be the disinfection of all sputa, pocket handkerchiefs, etc.

and eventually to stamp out all inflammations?

Immunity through inoculation of attenuated virus, albumens and ptomaines.—It has long been known that all animals constantly give off poisons which, if accumulated, are fatal to their own existence.

Certain vegetable ferments which produce alcohol, are said to be rendered inactive by the presence of no more than 2 per cent. of alcohol.²¹

Pasteur says: "Many microbes seem to give rise in their cultures to substances which have the property of being harmful to their own development."²²

There seems to be a universal law that all living organisms form poisons to themselves; and there is good foundation for the hope that there may be found methods of using those poisons for the destruction of those microorganisms which cause diseases of man, or otherwise for the prevention of those diseases.

Immunity against Rabies.—Prof. Welch says: "There can be no doubt whatever that it is possible to render animals immune against rabies both before and after inoculations which would otherwise cause the disease. The independent and careful experiments of Ernst in this country are free from all partisan bias, and have fully confirmed the statements of Pasteur and others upon this point."²³

Prof. Henry Sewall, of the Michigan University, demonstrated the possibility, through injection of snake poison, of rendering the organism immune to the bite of the rattle-snake.²⁴

The experiments and practices of Pasteur and others, for the purpose of securing for mankind immunity from dangerous communicable diseases, through the inoculation of the body with the attenuated virus of such diseases, have, for several years, kept this subject before the people, and there has seemed ground for the hope that eventually success would crown the efforts being made in this direction, and if once the principle is learned with reference to one disease, then there is hope with reference to the other diseases. But nearly all such efforts have been made by individual workers, at their own expense, and in such irregular times as they are able to take from their regular avocations by which they maintain them-

²¹ "Immunity through Leucomaines," by Eusebio Guell Baigialupi. Translated from the second French Edition by R. F. Rafael, M.D., J. H. Vail & Co., New York, 1889.

²² Comptes Rendus. Séance du 20 October 1885, p. 771. M. Pasteur said.

²³ As far back as the year 1880, I had instituted research in order to establish the fact, that the microbe of chicken cholera produced a sort of poison of this microbe.

²⁴ One would say, that immediately, there springs into existence a product which arrests the development of the microbe, whether cultivated in contact with the air, or in a vacuum.

²⁵ Mr. Raulin, my former assistant, to-day Professor to the Faculty of Lyons, has shown, in the remarkable thesis which he sustained at Paris March 22, 1870, that the vegetation of the *Azobacterium* develops a substance which arrests, in part, the production of this mold when the nutritive medium does not contain salts of iron.

²⁶ William H. Welch, M.D., Trans. Maryland Med. and Chirurg. Faculty, April, 1889, pp. 170, 171.

²⁷ Mentioned in British Med. Jour., November 20, 1889, p. 1264.

selves. A few workers have been employed by Governments, but there is no such Governmental support of such investigations as the immense importance of the subject demands, and especially not in our own country. The United States Government can be commended for what it does in this direction relative to the health of *domestic animals*, but what *can* one say, by way of apology for a Government that appropriates hundreds of thousands of dollars to study the causes of diseases of domestic animals, and then fails to appropriate as much to do a similar work for the lives of the people? I wish, however, to commend what has already been done by the U. S. Government.²⁵ I have already mentioned what it has done for quarantine; but I believe there is promise of great good to the human species as a result of the Governmental researches into the causation of diseases of animals. The work of Drs. Salmon, Smith and Schweinitz, of the U. S. Department of Agriculture, looking to the production of immunity in animals exposed to hog cholera, has added greatly to our knowledge of the underlying principle in the production of immunity to dangerous communicable diseases of animals and of man.

Dr. Welch has said: "That immunity against infectious diseases may be secured by the injection of chemical substances produced by the growth of specific bacteria, was demonstrated first by Salmon and Smith in the case of hog cholera, and has since been demonstrated by Ronx and Chamberland for malignant oedema, and by Wooldridge for anthrax,"²⁶ both dangerous diseases of man as well as animals.

Published accounts of experiments by Dr. Schweinitz,²⁷ and also by Frederick G. Novy, Sc.D., at the Michigan State Laboratory of Hygiene, indicate that by the inoculation of an animal with the albumens and ptomaines formed in culture liquids by the life-processes of the germs of hog cholera, the animal becomes insusceptible to hog cholera, whether exposed to the disease by inoculation or by direct contact and association with animals sick with the disease. Dr. Schweinitz was even able to produce immunity in an animal by inoculation with a pure chemical prepared synthetically in the laboratory. The results of these experiments are in harmony with facts already known.²⁸ Perhaps the term "attenuated virus" may still be used if we consider that the "attenuation" consists in the destruction of the germ, and in the saving of its products for use in the production of immunity. Of course much remains to be done before this knowledge can be

made directly available in the prevention or restriction of dangerous communicable diseases of man, and the sooner that work is done the sooner the thousands of human lives now lost through those diseases may be saved. Such work is for the general good, and should be done by the General Government. It should be done with reference to diseases of man, and not confined to diseases of animals, nor even to diseases which, like rabies, affect man and animals.

Is it not time that human life should be recognized as a proper object, and the most important object of solicitude on the part of the National government of the United States?

It will be a great gain, however, if it can be brought about that the government shall do such work, even if only for the saving in money values to the people, which, undoubtedly, would be immense.

Antidotes to Diseases Already Acquired.—At the recent International Medical Congress in Berlin, Dr. Koch, of the Imperial Board of Health, referring to his now famous consumption cure, said: "My researches on this substance, therefore, although they have already occupied me for nearly a year, are not yet completed, and I can only say this much about them, that guinea pigs, which, as is well known, are extraordinarily susceptible to tuberculosis, if exposed to the influence of this substance, cease to react to the inoculation of tuberculous virus, and that in guinea pigs suffering from general tuberculosis even to a high degree, the morbid process can be brought completely to a standstill, without the body being in any way injuriously affected." . . . "This opens up an oft-promised field of work, with problems which are worthy to be the subject of an international competition of the noblest kind." . . . "Allow me, therefore, the expression of a wish that the nations may measure their strength on this field of labor and in war against the smallest, but the most deadly, foes of the human race; and that in this struggle for the weal of all mankind, one nation may always strive to surpass the other in the successes which it achieves."²⁹

Certainly we can all join with Dr. Koch in such wishes for National effort for life-saving work; but I think that, among all the countries represented at the International Congress, there are few governments which occupy such an enlightened position on the subject of sanitary researches as does the German Empire. If our own National Government would even do as much as to publish and thoroughly disseminate among our people the important results of the researches made by the German Imperial Board of Health, our people would have cause to rejoice, and probably thousands of human lives would be saved through the knowledge thus obtained. Some-

²⁸ The substance used by Dr. Koch for the eradication of consumption is not yet made known, but it may be expected to be in line with these facts.

²⁹ Journal of the Am. Med. Association, Vol. xv, No. 10, Sept. 6, 1890, p. 370.

thing in the direction of such publication has recently been done by the U. S. Marine-Hospital Service. But much more than has yet been attempted should certainly be done in that line. And if our government were to wake up to the importance of doing what the highest interests of its constituents demand—cause researches to be made for the creation of such knowledge—it can find as bright intellects and as faithful workers among our own scientific men as there are in any country; and in a short time the world might be as much indebted to the United States Board of Health for life-saving knowledge as it now is to the Imperial Board of Health of Germany.

While we accord great honor to Dr. Koch, who discovered the specific cause of consumption, and who now thinks he has discovered its antidote, let us not forget that it was an honored member of our own Association, our President in 1887, Dr. Sternberg, of the U. S. Army, who first discovered the specific cause of pneumonia, a disease which, as a cause of mortality in this country, ranks only a little lower than consumption; and, if the subject were followed up, it should yet yield results somewhat comparable with those reached by Dr. Koch with reference to the somewhat similar disease which he seems to have conquered.

Let us consider for a moment the prospective importance of such a discovery as that suggested by Dr. Koch: It is not claimed that all deaths are reported in this country, but the reported deaths in the United States from that one disease, consumption, in the single census year 1880 were 91,270; without doubt more than 100,000 such deaths occur in the United States in each year. If, as stated by Dr. Koch, "in guinea-pigs suffering from general tuberculosis even to a high degree, the morbid process can be brought to a standstill, without the body being in any way injuriously affected," there is certainly ground for the hope that something approaching that can be done for the human being, and that, if sufficient intelligent effort be put into the research, the substance which will do this can be found, even if it has not already been found by Dr. Koch. Let us suppose that our own National Government were to pay for such researches, and that annually the lives of one-half, or even of one-fourth of the 100,000 of our people, who otherwise would have prematurely died, were to be saved. How would that compare with the work of the Agricultural Department of our government, for the distribution of garden seeds? How would provision for such work by Congress compare with its work for the protection of our infant industries? How would it compare with any work that has been done by Congress during the past twenty years? I admit that in 1879 it established a National Board of Health; but the government failed to sustain the Board long enough to per-

mit of many such researches as those I suggest, although, as long as it was sustained, it did excellent work.

In comparing public-health work with the work of the U. S. Agricultural Department, I do not forget that—

That art on which a thousand millions of men are dependent for their sustenance, and two hundred millions of men expend their daily toil, must be the most important of all,—the parent and precursor of all other arts.³

But all must concede that agricultural art has now made such wonderful progress that there is no longer need for more, to fully sustain not only the necessities of man, but to supply many luxuries. Superfluous effort, therefore, might well be diverted from agriculture, to supply those provisions for public-health work for the want of which hundreds of thousands of our people actually prematurely perish, and hundreds of thousands more drag out a miserable existence.

So many of our people are now raising farm products, that that is claimed to be a comparatively unprofitable occupation.

Apparently, then, this country needs fewer farmers, more sanitarians.

We welcome to our ranks, however, not only farmers, but all good people.

They have departed, but their works continue.—Custom and humanity dictate that there shall be public recognition of the services of those who have publicly labored with us, and who have ceased their labors, but whose good work will go on down through the ages. Considering our numbers, and the average age of our members, it is to be expected that in every year death will overtake some of us. Before the time for our next meeting, some of us will have passed over to the "great majority." Since the last meeting, so far as I know, only three of our members have died: Dr. Charles Linnæus Allen, Secretary of the State Board of Health of Vermont, who was elected a member of this Association in 1888; Dr. J. H. Baxter, Surgeon-General of the U. S. Army, a member of this Association since 1876; and Dr. William Brodie, President of the Board of Health of Detroit, Michigan, a member of this Association since 1873. Dr. Brodie had long been a prominent member of the medical profession; he had been President of the State Medical Society of Michigan; and President of the American Medical Association. It was largely through his work that this Association held its successful meeting in Detroit in 1883. Dr. Brodie was President of the first Sanitary Convention held under the auspices of the Michigan State Board of Health.

I trust that a committee or the Secretary of this Association will make fitting records of the

³ James F. W. Johnston.

services of our deceased brothers, and of tributes to their memory.

Death of Sir Edwin Chadwick.—Since our last meeting, sanitary reform has lost an able advocate, in the death of Sir Edwin Chadwick in England. In recording his death, the *British Medical Journal* said:

Few men have deserved better of their country than the veteran sanitarian whose death, at the advanced age of 91, we have to record. His investigations of the sanitary condition of London, dating back to 1817, were the official starting point of a reorganization of the Health Department, and laid the public legislative basis of the first of a series of sanitary reforms which have been of inestimable value during the last half century in the saving of life and diminution of sickness and disablement. His subsequent services to the cause of army health reform, and his continuous devotion to great and small questions of public and personal sanitation, placed him quite in the first rank of non-medical sanitary reformers.

It has been aptly observed that had he, as a military man, succeeded in destroying one-hundredth part of the lives which he was prominent in assisting to save, his statue would have been erected long since in more than one of the great cities of the empire, and he would have been loaded with honors and titles. As it is, it was not until he attained the age of 90 that he received the honor of knighthood.³¹

Practical Application of Sanitary Science.—I have already touched that subject which was declared the second object of this Association, but mainly to show that the most rapid advancement of sanitary science is made, and is to be expected, where governmental aid is most complete and abundant; in other words, where the people as a whole contribute, according to their means. Having left the subject of advancement of science, I will briefly consider such "organizations and measures for the practical application of public hygiene."

State Boards of Health.—There is reason for a high degree of pride in the wonderful development, in this country, of the State Boards of Health. Although none of them have anything approaching the resources which are placed at the disposal of the Imperial Board of Health of Germany, or of the Government Board of England, and it must be confessed that the debt which humanity owes to Dr. Robert Koch, of the German Board, is perhaps greater than to any man in this country, in any field of human effort, still I think it can fairly be claimed that some of the State Boards in the United States rival the boards of health in the general governments of the most enlightened countries in the world—rival them in the amount of useful services which they are continually performing for their own people and for the general sanitary enlightenment of the world; especially do they rival them in the immediate practical results of their work.

For instance, statistics which appear to be trustworthy, seem to prove that in one State, and apparently through measures inaugurated and main-

tained by the State Board of Health, the deaths from small-pox have been so reduced that more than one thousand five hundred persons have continued to live who would have died from that disease if its mortality rate had continued as it was before the establishment of the State Board of Health. A thousand five hundred lives saved from small-pox means a saving also of at least six thousand cases of sickness from that loathsome disease.³²

In that same State, also, the vital statistics seem to prove that through similar though not identical work, there has already been a saving of life from scarlet fever equal at least to five thousand persons, and (if the death-rate was ten per cent.) a probable saving of fifty thousand cases of sickness from that disease.³³

Nor is this all; statistics indicate that at least *one life a day is being saved* in that State by measures started and maintained by its State Board of Health for the restriction of diphtheria.³⁴ As the death-rate is about twenty-four per cent., at least fifteen hundred cases of sickness from diphtheria are prevented annually.

At least one other State (Massachusetts) has undertaken statistical effort to learn the effect of such work, and similar saving has been made apparent.

It seems desirable that other States, in which similar work has been done, should collect and publish evidence of the results of their work.

The Value and Importance of Statistics.—On many questions of public policy, no useful conclusion can be reached without a thorough knowledge of the facts involved. And frequently it is important to have accurate knowledge respecting several classes of facts. For instance, in order to know what disease it is most important that we shall strive to prevent, it is necessary to know what disease causes the most deaths, or the most suffering among the people. Mortality statistics supply this knowledge. Again, in order to know whether a disease which is an important cause of death is itself caused by climatic or meteorological conditions, it is necessary to have, and to compare with the statistics of deaths and of sickness, other statistics relating to the various meteorological conditions.

For several years we had at Washington a United States Commissioner of Labor, and he has collected valuable statistics on the various branches of the subject of human labor. We ought to have at Washington an officer charged with the duty of collecting statistics relating to those subjects which bear directly upon human life and health.

There is now a "Department of Labor" in the

United States Government. Should there not be a "Department of Life and Health?"

Statesmanship.—This is an age of organizations among the people, for the general benefit of all. People generally are coming to have that degree of intelligence, education and culture, which fit them for self-government. The daily papers, the magazines, the excellent postal facilities, the telegraph and the telephone, have served greatly to equalize the intelligence of the people generally; they have served greatly to do away with famines, with continual warfare, and, I believe, with great wars; and certainly they have done much to make the old-time plagues and pestilences horrors of the past.

Yet, although the general governments of countries are making progress toward conforming to the actual conditions among the people, old customs and precedents have a powerful influence in restraining progress; and I think this is more noticeable to members of this Public Health Association than to any other class of people; for the reason that sanitary science is a comparatively new science, and has not for so long a time been available for spreading its knowledge among the people. But already the leading minds in several of the most civilized countries have recognized the fact that the greatest good to the greatest number of citizens consists, first of all, in securing to them life and health. Thus, for instance, Disraeli said that action in this direction "is the wisest statesmanship." Gladstone has expressed himself similarly. And, through the lead of such statesmen, England has its useful general board of health—the "Local Government Board," with its corps of medical officers. Some of the important work of the German Imperial Board of Health is well known.

In our own country, the framers of the Declaration of Independence declared that "life, liberty and the pursuit of happiness" are "among the unalienable rights," to secure which "governments are instituted among men."

In times past, the minds of men and of governments have been kept so occupied with protecting the lives of their citizens from the dangers caused by the battling of other men, hostile tribes, and foreign governments, that little time or energy has been left to devote to the protection of life and health from ordinary preventable causes of death and sickness. Now that men and nations are coming to be less destructive of each other, it is rapidly coming to be seen that by organized effort and general coöperation a great proportion of the premature deaths, and of the sickness from the most common diseases, and the resulting pauperism, insanity and crime, can easily be prevented; and this without any radically new principle of government, but by an extension of the principle of protection of life and property, into new systems of effort. The constitution gives

Congress the power to "provide for the common defense and general welfare of the United States."

It is the same now as when the book of Hosea was written—our "people are destroyed for lack of knowledge,"³⁵ and a government has only to collect, search out, and disseminate among its people "knowledge" of the causation of disease, its modes of spread, and how to avoid causes of deaths and the spreading of epidemic diseases, to make it possible for its people to have safety to "life" and that "pursuit of happiness" which is only possible to persons in health. This implies, however, that the government must constantly maintain statistical investigations and scientific researches into the causation of diseases, and such a complete and thorough system of prompt notification of the outbreak of every dangerous communicable disease within its own country—and also in all parts of the world where it may readily spread to its own country—that the government shall be able to and shall in fact promptly warn all its people endangered, and not only warn them, but shall at the same time place before them the best that is known or can be learned concerning the exact methods for avoiding the dangers to life and health from that particular disease which at the time is threatening.

Only by some such modification of governmental methods is it possible to do for a people that service which it is the highest function of a government to perform.

We hear much about the wisest statesmanship as applied to such questions as relate to our commercial dealings with other nations, questions whether it is wiser to have "free trade" or "protection" of home industries; yet these are questions of small consequence to the people of any country when compared with questions which involve the protection of the lives and the health of the people themselves; because the people can get sufficient food and other necessities for subsistence under "free trade" or under "protection;" but under neglect of proper governmental protection of life and health, a large proportion of the people prematurely die, and still larger proportions suffer sickness, life-long pain, and physical and mental degradations, from causes which under proper governmental protection are easily preventable. That this is true, there is no longer question; incontrovertible facts are on record proving that it is strictly true. As soon as this knowledge comes to a majority of the people, they will surely demand that the government shall no longer neglect its highest functions; and we may confidently look forward to a "good time coming" when the *safety of life to our people* shall be the first and most important concern of the enlightened government of these United States; when the most important officer in this country, whether he is called Commissioner of Health,

³⁵ Hosea, chapter iv, verse 6.

Secretary of the Health Department, or President of the United States, shall, at all events, be its wisest sanitarian, or at least its most competent public health administrator. And you, the members of this Association, are and should be laying the foundations, and fitting yourselves for the performance of such highest and most sacred duties; for, in these days of rapid advances in the spreading and equalizing of knowledge, we know not how soon the clamor of our people, for the protection of their lives, may force upon our own National government the proper performance of its highest duties, which it has so long neglected.

BORACIC ACID AND MASSAGE IN PANNUS.

Read in the Section of Ophthalmology at the Forty-first Annual Meeting of the American Medical Association, held at Nashville, Tenn., May, 1896.

BY C. R. HOLMES, M.D.,

OPHTHALMIC SURGEON TO THE CINCINNATI HOSPITAL; CLINICAL LECTURER ON DISEASES OF THE EYE, MIAMI MEDICAL COLLEGE; PROFESSOR OF OPHTHALMOLOGY TO THE WOMAN'S STATE HOSPITAL MEDICAL COLLEGE.

The treatment of a limited number of affections of the eye and its appendages by massage is, as is well known, not new, and to Donders belongs the honor of having first proposed it, at the Ophthalmological Congress in London in 1872.

Massage has been practiced with or without the addition of ointment; but Landolt was, so far as I know, the first to systematically use boracic acid and massage in granular affections of the conjunctiva and cornea.¹ Acting on this suggestion, I began last year to make observations on a number of cases, and present herewith the results.

New methods and remedies are too often lauded far above their real worth, but after nearly a year's trial, I am satisfied that in the treatment of pannus, whether acute or chronic, it is most valuable, especially when used in connection with one or more of the standard remedies directed toward curing the lid affection. Its chief value lies in the rapidity of its action, a few days frequently giving as good and often much better results than as many weeks by the usual methods.

I have also tried it in cases of granular and follicular conjunctivitis where there was no corneal affection, selecting cases where the inflammation was, so far as I could determine, equal in both eyes, treating one eye with boracic acid powder and friction, and the other with the usual astringents. For a few days after instituting the comparative treatment, the eye receiving massage would appear more improved than the other, but after that the treatment by astringents would lead while the other would either appear stationary or

recede, till the plan was abandoned, and the old reliable remedies used in both eyes.

I now use a 5 or 10 per cent. solution of cocaine as an anæsthetic, then evert the lids and separate them as much as possible with one hand, while with the other, by means of a camel's hair brush, as much powder is dusted into the eye as it will contain. Then, by grasping the edge of the upper lid with thumb and index finger, replace the lid in such a manner that the powder will be retained between the cornea and the lids. With the index finger or thumb massage is then begun. I do not anoint the finger as has been recommended for simple massage, for we desire the friction movement to take place between the lid and the globe, which at best is only limited if the globe is stationary. Cocaine gives the patients, as a rule, control of the movements of the eye, and I direct them to look in such direction as will bring the cornea under the finger. In many cases the cornea rolls upwards, and we must endeavor to follow the position with the finger.

The friction should be continued from one to five minutes to each eye, the duration depending upon the density of the pannus and whether it be of long or short standing.

My cases are about equally divided between private, hospital and clinic patients.

Case 1.—Master B., æt. 12, a typical case of severe granular conjunctivitis of four years' standing, with dense pannus. During last three months had to be led about. Much photophobia and lachrymation present on examining the eyes. Can only see movement of the hand in front of his face. The sulphate of copper crystal and atropine was used two weeks, with improvement of lids but not of cornea. Changed to boracic acid and friction, and from day to day we could see the cornea clearing up. In one week vision became $\frac{20}{200}$. The lids during this week received no other treatment and began to look worse, when the mixed treatment was continued from that on until his corneæ were clear and he went to his home in the country. Duration of treatment ten weeks. When discharged he could, with a little effort, read ordinary print.

Case 2.—Mr. R., æt. 45. Contracted granular conjunctivitis four years ago. *Status Præsens:* Lids present the ordinary cicatricial alterations of a well-marked case, having almost completed its course. But the upper third of cornea, especially outer quadrant, is covered by a thick, flesh-colored mass extending upon the sclera for a distance of $\frac{1}{4}$ inch, where it gradually begins to become thinner. At this point the follicles become plainly visible, assuming a straw color, gradually fading into the normal ocular conjunctiva. The family physician was inclined to regard it as malignant. The other cornea showed the effects of pannus in the form of extensive

¹ See *Annals of Universal Medical Science*, 1889, Vol. iv., p. B, 70.

nebulae becoming denser in the upper third, but there is no acute inflammation about this eye. Boracic acid and friction was instituted twice daily, duration five minutes at each sitting, pain controlled by repeated instillations of cocaine. After each treatment there was great vascular activity, which soon subsided. After three days one could notice slight improvement. Patient returned home, where his physician carried out the treatment once daily for three weeks, when he returned with the mass three-fourths absorbed. Another two weeks' treatment at my office was sufficient to remove the mass entirely, leaving central portion of cornea clear, upper portion slightly cloudy, but quite smooth.

I have the records of fifteen other cases treated by this method, but will not take your time nor try your patience by a repetition of results, but I only say in conclusion, that I am fully aware of the fact that but little value can be placed upon conclusions drawn from treatment of a few cases. I only offer them for your consideration, being the result of careful, painstaking observation; and hope during the coming year to continue my investigations, profiting by the views and experience of others.

The good results I have obtained from this method of treatment, I attribute to a mechanical cause, viz.: the friction, thus bringing about increased arterial and venous circulation, breaking down degenerated epithelial masses and forcing open occluded lymph channels, thereby preparing the way for rapid absorption of pathological products.

I believe that any other powder equally palatable and unirritating would do as well as boracic acid.

HEMORRHAGE FOLLOWING EXTRACTION OF A BLACK CATARACT IN A HIGHLY MYOPIC EYE, PROBABLY ASSOCIATED WITH CHOROIDAL CHANGES; ENUCLEATION.

Margaret S., æt. 53, widow, good physique, habitual user of strong drink, admitted to Cincinnati Hospital October 23, 1888. States she has been very nearsighted since childhood. About six years ago she noticed vision failing in the right eye, and since four years the left has slowly followed the same course. By ordinary inspection with pupils dilated by a mydriatic, cataract appeared, almost black in the right and grayish-black in the left eye. Cornea, aqueous humor, iris and tension normal in both eyes. The ophthalmoscope reveals total opacity of both lenses, by candle test field of vision is very defective centrally, fair at periphery in the left eye, while in the right she is unable to locate the candle over a large portion of the right half of field. Heart, lungs and urine normal.

October 27. Under cocaine I extracted the right

lens without iridectomy. Lens very large, black and hard, when placed on a piece of white paper only the very margin permitted any light to be transmitted. Healing process not attended with the slightest inflammatory reaction. On the third day patient was permitted to sit up, pupil responding to light. Discolored capsule gives pupil a grayish appearance.

November 10. Under cocaine made a liberal but distinctly corneal incision upwards; liberal because, in extracting the right lens, I underestimated its size and hardness, making its exit through the corneal incision somewhat difficult. After lacerating the capsule and beginning manipulation for expulsion of lens, a hernia of iris and vitreous presented in the wound.

I at once made iridectomy, and delivered a large, black and hard lens without further complications. There was only slight bleeding from the cut iris, the blood being readily expelled, leaving a black key-hole pupil. Figure of a bandage was applied. The eye felt comfortable till two hours after the operation, when patient had an unpleasant feeling in the eye, became sick at her stomach and vomited, pain in the eye becoming very severe. The interne found the bandage saturated with blood, some of it trickling down her cheek. The pain was controlled by hypodermics of morphine. Next morning I found swelling of lids, and on exposing the globe discovered a large mass of blood stained vitreous protruding from the corneal wound and slight bleeding still going on. The hernia was not abscised for several days because patient refused to have it done. There was slight oozing of blood for five days. No microscopic examination was made of the abscised hernia, and I am unable to state whether or not it contained portions of the retina. The shrunken globe was tender and irritable, enucleation was advised, but refused at first. Six weeks later she consented to enucleation, as the tenderness still continued. The eye was removed by Dr. Robert Sattler, who was then on duty.

When seen three months later the capsular opacity, in the pupil of the right eye, was still sufficiently dense to prevent seeing the details of fundus. In this condition her vision was about $\frac{2}{20}$ —not improved by convex lenses. Discission was of course the proper thing to do, but on account of my experience with the other eye, I delayed, and when later on I sent for her to go into the hospital to have the operation made, I found she had left the city. I regret having lost sight of the case, as I was desirous of obtaining a good view of the fundus in order to determine the existence or non-existence of choroidal alterations. Whether the color of the cataracts was due to former intraocular hæmorrhage, or to simple densification of all the cortical substance, I am unable to state.

THE COLITIS OF INFANTS.

A Paper prepared for the Cincinnati Academy of Medicine

BY JAMES M. FRENCH, A.M., M.D.,

LECTURER ON MORBID ANATOMY AND DEMONSTRATOR OF PATHOLOGY AT THE MEDICAL COLLEGE OF OHIO; PHYSICIAN TO ST. MARY'S HOSPITAL, CINCINNATI, O.

Acute colitis, in the sense of an acute catarrh of the large intestine, occurs in infants as a primary disease or as a part of the affection which has received, among other names, the designation enterocolitis. If, in what I have to say of it in the latter connection, I shall appear to make an unnatural separation of usually associated lesions, I hope to be excused on the ground that I believe that colitis is a part of the disease which is too often lost sight of, particularly in the treatment of it.

It is in this connection with catarrh of the small intestine that the disease is most frequently encountered. It then occurs as a sequence of cholera infantum, or of an acute dyspeptic diarrhoea.¹

In its primary form colitis is usually due to errors in diet, especially when it affects infants which have passed the weaning period. Occasionally it complicates other diseases, as the acute exanthemata, or arises from the irritation of foreign bodies or parasites in the bowel. It begins, in some cases, gradually, and runs a mild, nearly or quite afebrile course of a few days' duration; in other cases, it begins with sudden alarming symptoms, rapid rise of temperature to 103° or 105°, great prostration, nervous excitation, even convulsions, with frequent, small, bloody stools, consisting largely of mucus. It may then speedily terminate in death, or may last for weeks or months. It so much resembles, in its general features, the dysentery of adult life, that some authors have used the latter term in its description. True dysentery is, however, rare in infants.

The enterocolitis which follows the acute stage of cholera infantum is like a broken truce, or the siege which follows an unsuccessful engagement. The more alarming symptoms of the disease have passed away. The temperature has returned to the normal; the nervous phenomena have subsided; strength and appetite have in part returned; the stools have become more consistent, and the child's appearance has begun to indicate that convalescence is near. But the child continues restless, begins to have pain and is peevish. Fever again appears, ranging, as a rule, from 101° to 102°. The stools become smaller and more frequent. They consist of undigested food, mucus, and as a rule, a variable amount of blood. The odor is fetid in proportion to the quantity of undigested and decomposed food which they contain. The disease now has a tendency to persist, or to recur at short intervals, and often presents the features of inflammation of the large bowel, rather

than of the small. When it is persistent, the frequent, small, painful, bloody stools continue day and night. The little patient gets no rest, until, if the disease be not checked, after from three to six weeks, he is relieved by death. When the disease is more remittent in character, there is a gradual failure in strength and loss of flesh, until the little sufferer has become extremely emaciated. His facial expression is that of an aged person, and his integument, often dry and scaly, seems too large for his wasted frame. The duration of the disease in this form is indefinite. Beginning early in the summer, or under faulty hygienic conditions, it usually continues until the season or these conditions have changed. Ordinarily recovery is slow, and relapse is exceedingly common.

When enterocolitis begins with the so-called dyspeptic diarrhoea, there often appears to be almost from its inception a catarrhal condition of the entire intestinal tract, commencing in the stomach and passing, like a wave, along the entire mucous membrane. The symptoms are vomiting, followed almost immediately by diarrhoea, which, after from a few days to a week, almost always presents features characteristic of catarrh of the large bowel, the frequent, small, bloody, mucus stools that I have described.

Enterocolitis is therefore a disease which commences in the upper portion of the alimentary canal and progresses downward, rather than one that affects all portions at the same time. After the brief initiatory period, it as a rule affects only the lower third of the ileum and a greater or less portion of the colon. Unfortunately, the lesions which are found post-mortem in both cholera infantum and enterocolitis are not sufficiently constant to be entirely characteristic. Moderate hyperæmia, if it exist, is a condition which largely disappears at death, and extreme hyperæmia, although the rule, is by no means constant. Loss of intestinal epithelium, a much more constant finding in such cases, occurs as a rule in from six to ten hours after death, and is not pathognomonic of intestinal disease. But intense inflammatory processes soon lead to permanent changes. Follicular ulceration, and cellular infiltration of the mucosa, the submucosa and deeper tunics of the bowel are the common results of the prolonged catarrhal process under consideration. The point that I desire most to emphasize is the fact that lesions occur in the large intestine not only in a large proportion of these cases, but that their character indicates a severity of the diseased process which in most cases quite exceeds that found in the ileum.

That the mucous membrane of the colon should be thus often involved in the morbid process is almost axiomatic, since into the colon must pass the products of all pathological processes situated in the upper alimentary tract. Cholera infantum is variously accounted for, but owing to the fre-

¹ Holt's classification is here followed. * *Cyclopedia of the Diseases of Children*, Vol. III, p. 134.

quency with which microorganisms are found in the dejections and in the intestines after death, it has been pretty generally accepted that the disease is due to the action of bacteria which have not yet been isolated. By those who accept this theory, the symptoms are supposed to be due, for the most part, to the ptomaines produced by these bacteria. The local inflammatory process in the large bowel is doubtless in part due to the action of the same bacteria and ptomaines, but it is probably in part a result also of the abnormal fermentation of intestinal contents caused by other germs or by no germs. Chemical changes in all probability occur. The evidences of most intense inflammatory action are found in those portions of the colon in which the contents remain longest in contact with the mucous membrane, namely: in the cæcum, the transverse colon and in the sigmoid flexure. In the primary form of the disease, the lesions, the same in character as those described, are found for the most part in the sigmoid flexure and rectum.

The treatment of colitis is to be considered apart from that of affections of the small intestine only in the comparatively infrequent primary form of the disease. But even in cases of this nature, attention must be given to the character of the gastric and intestinal digestion. Incomplete digestion or abnormal fermentation of any kind may act either as an exciting cause of inflammation, or may tend to prolong its duration when once it has begun. Errors in diet must therefore be carefully rectified, and a diet suitable to the age of the patient must be selected. Only liquid food—milk and beef or mutton broths, is to be permitted. If constipation has preceded the attack, or if from the history of improper diet, the presence of flatus, or the character of the stools, the presence of abnormally fermented matter or other irritant substances be suspected, calomel in doses of from $\frac{1}{10}$ to $\frac{1}{2}$ gr. may be given every three hours until purgation is produced. In a majority of cases, little or no other treatment is required. Severe cases, however, require more active measures, in the manner to be described.

The treatment of enterocolitis is often exceedingly difficult, for here we have, in addition to the disease of the colon, an inflammatory state of the lower third of the ileum. Within a few days from the onset of the disease the little patient becomes prostrated and the signs of emaciation begin to appear. As the large intestine becomes involved, the frequent, often constant desire to defecate, the tormina and tenesmus, prevent sleep, and the condition often becomes alarming. How, then, can we relieve the patient from these symptoms, and what can we do to arrest the inflammatory process? The essential feature of the treatment at this stage is to so change the character of the intestinal contents that they shall no longer be irritating in character, and to give rest to the

inflamed mucous membrane. This is to be accomplished by correcting errors of diet, by overcoming defective digestion, and by arresting abnormal fermentation.

For the correction of errors of diet much is to be considered, the recitation of which would here be out of place. It is necessary that the child shall receive the proper quantity of the right kind of food at the right intervals for its age. Not seldom the error will be found to consist in the too early resort to a mixed diet, too frequent nursing, or the use of such inferior substitute for mother's milk as impure cow's milk, condensed milk, or an inferior quality of artificial food, or the use of improperly prepared food. The diet should consist of articles of food which are most certain to undergo easy and complete digestion, leaving as little residue as possible. The passage of healthy feces from the small intestine into the large in these cases is sufficient to excite peristalsis. For this reason, we must also carefully guard against over-feeding. Cold drinks must be prohibited, except the taking of an occasional teaspoonful or two of water to relieve the excessive thirst which is always present. A copious draught of cold water is almost inevitably followed by an evacuation of the bowel. Digestion may be facilitated by the administration of an active pepsin or pancreatine; and the addition of a small quantity of calomel tends to arrest abnormal fermentation. I have rarely employed any medicines other than those chosen in the following prescriptions:

- R. Pepsini (F. & F., or P. D. & Co.), gr. xij to xxiv.
Hydrargyri chlor. mitis, gr. ss to j.
Sacch. lactis q. s.
℞. ft. chartas No. xii.
S. One powder every three hours.

Or, in cases in which the intestinal digestion appears to be at fault:

- R. Extracti pancreatis (F. and F.), 5ss to j.
Hydrarg. chlor. mitis, gr. ss to j.
Sacch. lactis q. s.
℞. ft. chart. No. xii.
S. One powder every three hours.

It is better to give explicit directions that the powders be given immediately before or after nursing, and not oftener than once in three hours, as it is in this way possible to more completely rectify the error of too frequent feeding than by any other means, for our instructions as to the giving of medicine are more likely to be obeyed than are those pertaining to the correct manner of feeding the infant, a subject on which every mother has her own ideas. Naphthaline has been highly recommended for arresting decomposition, but although I have had excellent results from it in adults, I have used it in but two or three children. Its odor makes it difficult of administration. The advice of some writers to give small quantities of nourishment at short intervals is not judicious, as it both tends to embarrass diges-

tion and to increase peristaltic action. Ordinarily the diet of nursing infants may be restricted to the mother's milk, and that of infants that have been weaned, to sterilized cow's milk. But in severe cases, it is necessary to discontinue even cow's milk, for a time. By this means alone are we able to free the inflamed bowel from the influences which keep up the inflammation. The removal of food is by no means an easy task in most cases. Something must be given both to provide nourishment and to satisfy thirst. Mellin's food prepared with water instead of milk is well suited to this purpose, as it furnishes ample nutriment and leaves almost no residue in the bowel. In addition to this, an occasional teaspoonful of freshly expressed beef juice and a few drops of brandy may be given.

When the symptoms of catarrh of the large intestine greatly preponderate, thorough irrigation of the bowel is beneficial, even in young infants. It may be practiced with lukewarm water, a weak solution of common salt or alum, mercuric chloride (1:4,000), or nitrate of silver. The latter two remedies should be used, I think, only for their action on such parts as may be reached by the introduction of a recurrent catheter, the sigmoid flexure and rectum, owing to the danger of their retention. In some cases I have injected, after a short interval succeeding the irrigation, from 1 to 2 ozs. of warm starch water containing from 1 to 5 drops of laudanum, in infants of an age to justify the experiment. A much needed night's rest has thus been secured and the tide of the disease effectually turned. This procedure is, of course, not to be thought of until all products of decomposition have disappeared from the stools. The same result, so far as arrest of the symptoms is concerned, would follow the administration of an opiate by the mouth, but, although this practice has received the sanction of high authority, I cannot discern its propriety; since with the beneficial action will occur an arrest of digestion. In extreme cases I have used hypodermatically minute doses of morphia with atropia. The worst cases that are encountered are those in which opium has been injudiciously used in the early course of the disease.

By no means the least difficult period in the management of the case is that of convalescence. As the more severe symptoms subside the little patient develops a ravenous appetite, the gratification of which is one of the most frequent causes of relapse. Weeks or months, rather than days, are to be consumed in the return to the diet of health. The first step in the gradual restoration of diet in those cases which have required the suspension of all food, is the gradual addition of milk to the artificial food, until the normal proportion is reached. This then should constitute the diet for several weeks.

Hygienic treatment must of course be pursued,

the chief item of which is frequent bathing. If circumstances permit, the removal of the child from the city to the country will greatly hasten recovery.

THE CLINIC.

UTERINE MYOMA—RENAL CALCULUS AND SURGICAL OPERATIONS UPON THE KIDNEY.

*A Clinical Lecture Delivered at the Regular Surgical Clinic at
Kew Medical College, Chicago, Thursday, Oct. 2, 1890.*

BY CHARLES T. PARKES, M.D.,
PROFESSOR OF SURGERY.

(Concluded from page 52.)

If no information is gained by this examination, the kidney is fixed as much as possible in the wound by pressure through the anterior walls of the abdomen, and by forceps grasping the perinephritic tissue; then a grooved director is thrust through its substance towards and into the pelvis, which is examined thoroughly in all directions by changing the direction of the probe, until the stone is struck, or none is found. Of course, if, as in this patient, the tissue of the kidney and its pelvis is distended with pus, as soon as the director enters the cavity the pus will flow through its groove, as you see it does in this instance.

The blunt-pointed director is the best instrument to use in this trial; it, or any other cutting instrument, should always be introduced into the kidney some little distance above the lower end of the organ, on account of the frequency of the presence of the artery aberrans entering the organ at this point, and the free hæmorrhage attending the wounding of it. It is also said that fatal hæmorrhage has followed the use of the pointed aspirator used for this purpose, the needle being thrust so far forward as to puncture the main renal artery or vein.

No attempt should be made to fix the kidney by means of forceps attached to its substance, or by threads passed through it, because, owing to the structure of the kidney tissue—its softness and brittleness—they will surely tear out; no fixation will be obtained, merely unnecessary damage done the organ. It can sometimes be fixed very well by passing the finger behind it in the wound.

In case no pus escapes along the groove of the director, as not infrequently happens when the kidney is not much increased in size, and it is thought necessary to make further exploration, a scalpel is carried along the groove of the director through the substance of the kidney, making an incision large enough to admit the finger easily; the finger is passed through it into the pelvis of the kidney and a careful search made in all directions for the foreign body.

If the stone is of large size, filling and distending the cavity of the pelvis, the examination by palpation of its entire surface, as already described, will have probably discovered its presence; in which event the knife is carried directly through the substance of the kidney to the stone, and the proper incision made. If the stone is discovered by the use of the director, without any flow of pus, an opening is made by the knife sufficiently large to admit the finger.

In this patient, in which pus is found to be present, after the introduction of the director, the incision should be made as free as possible, not only for the removal of the stone, but especially to lay open freely the pouches which are so apt to be present in these cases. This will provide for free drainage and prevent the retention of pus in these pockets, as the kidney contracts after operation, leading to the occurrence of secondary abscesses so common in the history of suppurating kidneys.

How will you proceed after the finger has touched the stone, no matter by what method it has reached it? The calculus is carefully and slowly loosened from its bed, by keeping the pulp of the finger in contact with it, and pushing the investing tissue away from it by the finger nail carried in all directions, until the stone lies perfectly loose in the cavity. Then a pair of dressing forceps introduced along the finger, is made to seize the stone firmly, and it is drawn quietly and slowly through the wound until its removal is accomplished.

The directions about removing the stone are thus minutely given, because it is especially desirable to remove it entire, and thus avoid leaving any small pieces, which, owing to its brittleness, can be easily broken off. They often avoid the most rigorous search and become the nucleus, around which may form other stones in the future.

Besides, the calculi are frequently very irregular in shape, having off-shoots developing from the main stem, in different directions, like pieces of coral. These off-shoots are firmly embedded in the calices of the organ or accidental pouches, so that they are easily broken off, and may remain embedded in these pockets if any forcible attempts are made to withdraw the stone before it is entirely loosened by means of the finger.

Of course many times the stone or stones, are found loose in the pelvis of the kidney, or in the cavity of the abscess, or they are smooth of surface and even and regular in their development, in which case there is no difficulty attending their removal.

In this patient, you notice that I have considerable difficulty in loosening the stone which we have found, and I am compelled to enlarge the opening in the kidney very much, because the stone is of large size and very rough and irregular in its shape. Now I think I have it

loosened and the incision made long enough to allow of its easy exit. Introducing this pair of forceps, the stone is seized, and while extracting it slowly and carefully, with my finger I push the kidney substance away from its irregular surfaces. Unfortunately I have broken this piece in the grasp of the forceps, away from the main portion of the stone, which accident not only spoils the beauty of the specimen, but shows you how brittle the concretion may be and how carefully it must be handled. There is no fear of this fragment causing any subsequent trouble because I have it on the outside. The stone is seized again with the forceps, at a larger, denser portion of its surface, and with the same careful method of extraction, it is finally removed entire.

The specimen is fully three inches long and over an inch in width at its widest portion. It is very irregular in formation and shows the presence of the off-shoots, to which your attention has already been directed.

The hæmorrhage is very free following the first incision made into the kidney substance, but in my experience, it has never been hazardous or sufficient to cause any anxiety, for the pressure of the finger, introduced through the wound, soon causes it to cease.

The manner of treating the wound is different according to whether pus be present or not. If there be no pus and the kidney not much enlarged, very little special treatment is required.

A large size drainage tube, long enough to reach into the pelvis of the kidney, should be introduced and left for a few days to provide for the easy exit of bloody serum and urine, which will flow immediately after the operation and as a consequence of it. The external wound is closed up to the drainage tube, by means of interrupted silk sutures passed through all the tissues of the edges of the wound in the same manner as in the abdominal operation, although in this operation, there is no peritoneum to be included in them.

The drainage-tube prevents the probability of the occurrence of urinary infiltration.

After a few days clear urine will flow through the tube, when it can be removed and the resulting sinus will rapidly close and securely heal by cicatrization, leaving nothing to mark the occurrence of such a severe operation, but the external scar. The urine passed from the bladder will show the presence of blood in a greater or less quantity for a few days, gradually resuming its normal condition. This symptom has its advantage, because it proves that the ureter is patent.

If pus is present, the several pockets in which it is apt to be contained are usually found to be separated from each other by incomplete trabeculae of connective tissue or kidney sub-

stance. These are broken down with the finger, thus converting the many into one cavity; this cavity is then thoroughly irrigated and washed with some mild antiseptic solution, such as boric acid or with sterilized water.

It is to be remembered, that solutions of powerful antiseptics, especially mercuric bichloride, contain in themselves the elements of extreme danger, in that they may poison the general system or seriously impair any normal tissue which may remain in the organ itself. Hence, if used at all, great care should be practiced and the cavity thoroughly washed out with sterilized water after their use. The use of bichloride of mercury sometimes leads to acute granular degeneration of the kidney.

The ragged portions of debris are then removed, and when thoroughly and satisfactorily cleaned, the cavity is packed to the bottom with iodoform gauze. No attempt being made to close the wound by suture. This treatment is advised, because it is my belief that it is least likely to be followed by secondary abscesses. In all conditions, the external dressing consists of the application of masses of loose iodoform gauze and borated cotton, held in place by a body bandage.

The operation, as you see, is prolonged, and hence likely to be attended with evidences of shock, therefore every provision should be adopted to counteract the dangers which accompany such conditions by the administration of quinine or whiskey before the operation; by keeping the patient's body covered with blankets during the operation and by providing artificial heat through radiation after the patient is put to bed.

The profession has come to the conclusion that chloroform is the best anæsthetic to use during all operations upon the kidney, but no matter what anæsthetic is used, the anæsthetizer should be careful to give as little of it as possible. Often allowing the patient to breathe freely of fresh air, by the removal of the cone, in this as well as in all operations which are prolonged and exhaustive in character.

Kidney stones are developed from the salts of urine, which are normally held in perfect solution and are oftentimes found to consist of the crystals of uric acid. Many are made up of oxalate of lime, while some are composed of phosphatic salts. They are found in both sexes and at all ages of life; they vary immensely in number and size, thus they may be so small as to pass easily through the ureters when loosened, and escape from the bladder; or so large as to change very greatly the shape of the kidney which is expanded about them. In form they may be smooth and even, or rough; or possess the greatest diversity in shape and irregularity of surface.

The symptoms indicating their presence have already been described to you as forming the history of an agonizing attack of renal colic. Still there may be no signs present indicating their existence, other than a steady, persistent, deep-seated pain, sometimes burning in character, referred to the region of the kidney, accompanied by the persistent presence of blood or pus in the urine. The suffering in these cases bears no relation to the size of the calculus—one patient from whose kidney I removed a concretion not larger than the end of the little finger, suffered repeatedly with excruciatingly severe attacks of renal colic, while in another with a larger calculus than the one removed to-day, the pain during such attacks was not severe.

These formations may take place in both kidneys at the same time, and when this occurs there is great difficulty in forming a conclusion on which kidney to operate, or whether to resort to surgical interference or not.

In all these cases, the microscopical examination of the urine is very apt to show the salts of which the stone is composed, present in the urine in large quantities.

If there is present a tumor in the region of the kidney, with the history of previous attacks of renal colic, there can be no doubt as to the diagnosis, and surgical interference should be practiced.

Treatment.—The treatment of these cases must be considered under three heads: prophylactic, palliative, and surgical. The latter has been illustrated to you in the operation performed upon the patient before you.

Prophylactic treatment consists in directing your patient's diet—avoiding the use of meats; and advising the free use of water, especially such mineral waters as are known to have a beneficial effect upon the condition of the system, termed lithiasis. The mineral water possessing the best effect is probably the one containing a large per cent. of the salts of lithia. It is my belief that large quantities of distilled water are beneficial. It is generally supposed that people living in countries in which the water used for all purposes contains a large portion of lime, are most likely to suffer from these troubles. It is also supposed that in children poor and improper food accompanied with faulty assimilative powers, have much to do with the production of the disease.

The palliative treatment has reference particularly to the management of the attacks of renal colic, the pain of which is controlled by the use of the preparations of opium, particularly the hypodermic injection of morphia, in doses of such size and sufficiently often repeated as is required to control the pain.

Frequently in severe attacks the careful administration of chloroform or ether to partial or com-

plete anesthesia is necessary to at least temporarily assuage the patient's agony until the foreign body has passed the ureter.

Hot fomentations freely applied over the painful area and the use of hot baths are beneficial. We know of no remedy, the administration of which through the mouth, will dissolve or in any way diminish the size of these renal concretions. No permanent relief can be given in any other way than by the removal of the offending body by surgical interference.

Renal calculi occasionally become lodged in some portion of the ureter; the most common place of stoppage seems to be near the point of termination of the tube in the bladder: at least quite a number of instances are on record in which the calculus forming in women, has been located in this position by vaginal examination, and their removal attained by operation.

If the stone becomes arrested at other points and cannot be located as in women, catheterization of the ureters can locate it; or if the kidney has become exposed in search of it, the passage of a sound from above will fix its position. When found it must be, and can usually be safely, removed by any operation which will expose its position. Of course any operation for this condition should be post-peritoneal.

The urinary fistula following such procedure is not usually permanent, but heals kindly and rapidly; every precaution for free drainage should be used to prevent urinary infiltration into the loose tissues in which the necessary incision is made.

Suppuration in the kidney and accumulation of pus dependent upon any other causes, such as tuberculosis or other degenerative changes, sometimes lead to the formation of various enlargements or tumors of the kidney which fluctuate freely.

The condition of distention of the kidney substance and its pelvis with pus, is technically called "pyo-nephrosis," and for its relief requires exposure of the kidney in the manner just illustrated. The abscess is then opened by free incision through the kidney. This operation is called nephrotomy. The treatment after the incision is the same as for cases of stone with pus accumulation. A similar distention, frequently reaching great size, follows injuries or diseases which occlude the ureter and there occurs the formation of a fluctuating tumor, the contents of which are clear, pale in color, and contain a slight evidence of the presence of urinary salts. This condition is called "hydro-nephrosis."

While the pus cases always show severe constitutional disturbance, with sweatings, chills, high fever, and other evidences of septic infection, hydro-nephrosis causes very little or no trouble until the increase in size calls attention to the tumor, and produces a varying amount of discomfort.

Aspiration, with a complete emptying of the cyst (for the kidney substance is so attenuated and thinned out it forms nothing but a cyst wall) will sometimes cure a hydro-nephrosis, at other times a cure will only follow free incision and drainage of the tumor by means of a nephrotomy.

In cases of pyo-nephrosis, as the result of pressure necrosis or ulceration from accumulation, the capsule of the kidney is destroyed and the pus leaks out into the surrounding cellular tissue, forming a peri-nephritic abscess, with the local signs of bulging of the space between the rib and crest of the ilium; with hardening and infiltration of all the tissues of the back in this space; with redness of the surface and edema and finally circumscribed fluctuation. The abscess points and breaks of its own accord or the surgeon incises it. Sometimes the opening in the kidney can be found, at other times not. If a fistula persists after the opening of the abscess, always suspect the presence of a calculus in the kidney. Expose and remove it by the proper surgical operation.

Pyo-nephrosis and hydro-nephrosis are classified under the head of cystic tumors.

There occasionally forms in connection with the kidney, simple serous cysts, and also those dependent upon the presence of the echinococcus or hydatid. Both of these conditions are successfully treated by exposing the tumor, incision and drainage or sometimes by simple aspiration.

It is quite surprising how seldom urinary fistulae persist even after very extensive incisions and bruising of the kidney. The urine may flow through the wound in the back for a few days or weeks, but if the ureter is patulous, they are quite certain to close. Wounds of this organ heal quite as rapidly and as permanently as those of any other tissue of the body.

The operation of nephrectomy or complete removal of the organ, is a very serious one primarily, and has dangerous sequelae attending it, even if the patient recovers from the operation, for the remaining kidney, called upon to do double duty, is particularly liable to the occurrence of diseases apt to be fatal.

It should always be remembered that the abnormality of one kidney is not very infrequent, or that the two may be joined together in the peculiar formation of a horse-shoe kidney, sometimes found present. A nephrectomy under these conditions would necessarily prove fatal. The operation should not be advised or undertaken except under the most pressing need, that is, in cases in which the disease or injury is of more menace to the life of the patient, than this hazardous operation.

It should also be remembered that even in advanced disease of the organ, in many cases, there still remains a considerable portion of the kidney substance, able to perform a portion of the normal

function of the organ; a patient with a badly damaged kidney, is in less danger, if some portion remains to do duty, than after the entire removal of the organ. Every means possible should be resorted to, to determine the existence of the abnormality of one kidney before the operation is done. Some surgeons recommend the catheterization of the ureters, in order to establish this fact; others favor what is termed abdominal incision—*anterior operation*—so that after opening the abdomen both kidneys can be found, before either is removed.

The first successful nephrectomy was done by Simon, of Germany, for an incurable fistula following a difficult parturition.

The disease for which the operation is recommended, are destruction of the kidney from suppuration resulting from any cause; or tuberculosis, if confined to one kidney; or cysts otherwise incurable; for the removal of solid tumors developing in this organ, and for such injuries as are followed by a persistent and incurable fistula; or which absolutely destroy the organ itself, as gunshot wounds.

The solid growths which we find developing in the kidney are, rhabdo-myoma, adenoma, papilloma, carcinomas and sarcoma; the sarcomas and rhabdo myomas occur oftenest in infancy or childhood. Adenomas and carcinomas are growths oftenest found in adult life. The sarcomas develop very rapidly and grow to a large size. Their removal is attended with many difficulties, and even if not primarily fatal, does not add materially to the patient's tenure of life. The same is true with the carcinomas with the exception that they never attain a great size, because their malignancy leads rather early to a fatal issue.

The adenoma are simple tumors; can be removed safely, and the patient's life may be prolonged in comfort for years.

There are two methods of performing a nephrectomy: first, the lumbar; second, the abdominal. The lumbar is the one most commonly chosen; the operative manipulations are executed outside the peritoneum; free and perfect drainage is easily carried out; and for these reasons it is best adapted for cases of suppuration in the kidney, and all tumors of moderate size.

The abdominal method is of diagnostic value in enabling the operator to at once decide positively that both kidneys are present; it necessitates an abdominal section, hence opens the peritoneal cavity—and no drainage can be practiced unless a counter opening is made through the loin. It is best adapted to the removal of tumors of large size, as it allows perfect control of the growth. The dangers attending both operations are first, hæmorrhage; second, infection; third, uremia from insufficient elimination of urine; fourth, shock.

Hæmorrhage can be avoided by special care in the management of blood-vessels; sepsis prevented by the usual aseptic or antiseptic precautions rigorously carried out; uremia counteracted by elimination and derivation through other excretories; and shock diminished to a great extent by free stimulation and protection of the patient from loss of body heat.

The lumbar incision for nephrectomy calls for exactly the same incision in all its details, as the one just practiced before you to-day, carried so far as to expose the tumor. After the organ is exposed it is loosened with the finger from its bed of perinephritic fat. As soon as this is accomplished, the blood-vessels entering the hilus are carefully isolated and a needle armed with a double ligature of sterilized silk is carried between the vein and artery, through the pedicle made by these vessels, dividing it into halves, and it is securely tied. The ureter is then sought after, temporarily secured with forceps and divided between them. The pedicle is then cut through, sufficiently far away from the ligatures not to endanger their security, and the kidney is removed.

In cases of suppurating kidney, the organ is often so firmly imbedded in vascular adhesions that bleeding is dangerously free during its separation. If this be the case it is best to ligate the main vessels first.

After the removal of the organ, the ureter may be managed in either of two ways. Its free end is made thoroughly aseptic by the application of the actual cautery or pure carbolic acid, and it is drawn out and fastened to the most dependent part of the external wound; or its extremity may be inverted into its lumen, like the finger of a glove, and the peritoneal edges fastened by sutures.

Quite large and vascular growths of this organ can be safely removed through the lumbar incision, by first securing the base of the mass with a temporary rubber ligature, drawn tight enough to close the blood-vessels. The tumor is then cut away piece-meal without bleeding until it is so far reduced in size that the permanent ligature may be easily applied inside the rubber tube, in the usual manner. The elastic tube is then removed.

Some operators include the ureter and the blood vessels in the same ligature, but the better plan seems to be to tie them separately.

If no pus is present, the wound is perfectly closed after providing for drainage by means of a large size drainage tube. If pus is present, the wound is best treated by the iodoform tampons as already described and illustrated to you to-day.

The dangers of this operation are increased by opening the peritoneum, and this accident should be carefully avoided.

When the abdominal method is practiced, an

incision is made through the linea semi-lunaris in the usual manner common to all operations which open the peritoneal cavity. The intestines are pushed out of the way by means of a large flat sponge.

As the tumor is behind the posterior layer of the peritoneum, this layer, too, must be incised before the tumor is exposed. The colon, in these cases usually lies on top of the tumor, and the incision which opens the posterior layer of the peritoneum should be made some distance away from the outer edge of the colon and parallel to it. It must be of sufficient length to allow the operator to have complete control of the tumor, and to provide for its easy removal. The sponge is then withdrawn; and the inner edge of the incision of the posterior layer of the peritoneum is sewed securely to the inner edge of the incision through the abdominal walls; in this way shutting off completely the peritoneal cavity from the field of operation. The blood-vessels entering the tumor are now sought after and ligated. The ureter is found and secured temporarily by forceps, the tumor separated from its attachments and removed.

It is just as well if the tumor is rather large and the space limited, to secure the blood-vessels temporarily by long jawed forceps, as they can be ligated inside of these after the removal of the tumor.

It seems best to always provide for drainage through the posterior lumbar region; this can be easily done and without fear of hemorrhage by thrusting a pair of scissors directly backwards to the interval between the last rib and the crest of the ilium and expanding their blades to make an opening through which a large drainage tube can be easily drawn.

The ureter is managed in either of the ways that have already been described in the directions for lumbar nephrectomy.

After the tumor is removed and the manipulations mentioned are satisfactorily carried out, the edge of the posterior layer of the peritoneum which was sewed to the abdominal wound is unfastened by snipping the sutures. The sponge is again used to keep the intestines out of the way while the incision in the posterior layer of the peritoneum is secured closely by means of the continuous catgut suture, thus perfectly isolating the peritoneal cavity from the large space recently occupied by the tumor. The abdominal wound is sutured in the usual manner, the sponge removed, and the external wound closed.

Nephrorraphy is the name given to the operation practiced for the relief of the symptoms accompanying a freely movable kidney.

It has only been during a few years past that the profession has adopted the belief that any operation is required for the cure or attempted cure of such cases. It is possible that it can be justly

said that it is only within a few years that the condition of a movable kidney has been recognized as the cause of a certain array of symptoms which interfere materially with the health and comfort of a patient suffering with this affliction.

Such patients as have come under my care have complained of quite serious trouble and have shown well marked evidences of failing health. All of them have become aware of the presence of the movable body and have insisted that the movements of the organ were the cause of much pain, at times even severe, and that the stomach was disarranged in its function—that the appetite was either lost or very much impaired—and that they had lost flesh noticeably and rapidly.

All of these cases had borne children—no doubt the condition occurs oftener in women who have borne children, still the condition is met with in men.

We know that normally, the kidney is not absolutely fixed in its position—that it is movable to a slight extent in its surrounding loose cellular tissue. For some reason or other after extreme distension of the abdomen its mobility becomes increased in these cases, occasionally to a considerable degree; a true meso-nephron is developed, at the end of which the organ has a range of motion in proportion to the length of the peritoneal fold. Probably such cases as possess a complete meso-nephron are the ones in which the severest pain is felt; which may be due to a twisting of the vessels and the ureter.

In some cases the kidney can be displaced downwards as far as the ilium, or inwards as far as the median line. It moves upon the slightest touch, and can always be replaced into the position in the back which it properly occupies.

The well known shape and contour of the movable kidney can usually be readily palpated with the fingers through the loose and flabby abdominal walls, and hence as a rule can be positively differentiated from any other growth.

If the kidney is only movable in the loose post-peritoneal fat, even if the area of motion is considerable, the operation for its relief is much more simple than in the cases in which the kidney is invested on all sides by the peritoneum, and has a long meso-nephron developed from this tissue.

In the first condition, probably a nephrorraphy will bring about a cure; in the latter, probably a nephrectomy will be required if any operation is demanded.

Most often the kidney is normal in every way except its freedom of displacement. At times it is diseased and enlarged, and this may necessitate the more radical operation. The long meso-nephron makes it very difficult or quite impossible to uncover the posterior surface of the kidney for the application of sutures without opening the peritoneum, an accident to be avoided.

This condition greatly increases the difficulty of finding or fixing the organ at the bottom of the wound made to expose it.

The prognosis as to the operation is favorable—in the matter of permanent cure it should be guarded. The operation has not been done often enough, the cases subjected to operation have not been sufficiently long under observation in all instances, to enable us to speak very positively about them. In my experience, they have all been noticeably improved at first, the appetite has been better, the food better assimilated and the pain relieved. But this favorable result followed during the confinement of the patient in the recumbent position, with little or no disposition to displacement or interference with the organ.

It remains yet to be seen whether the adhesions formed as the result of the operation, are sufficiently firm to withstand the weight of the organ and the influence of the movements of the body, when the patient assumes the erect position and performs ordinary duties.

It is quite fair to mention the fact that quite a number of cases have been reported by surgeons, in which, even after a lapse of two years, there has been no return of the displacement, and the general health of the patient has been permanently benefited. The primary incision for nephrorrhaphy is exactly similar, in all details, to that already illustrated to you to-day for exposing the kidney in the nephro lithotomy just finished. As soon as the peri-nephritic fat is uncovered, the kidney is found. Usually the assistant is able to fix the kidney in its normal position, by pressure against the organ through the anterior abdominal walls, so that it can be easily exposed to view by separating and displacing the surrounding fat. The posterior surface should be widely uncovered. Its capsule should then be incised for a length of two inches, and the edges of the divided capsule stripped off the surface for a short distance in opposite directions so as to uncover the small portion of cortical substance. Then the edges of the elevated capsule should be sutured with silk to the edges of the deep portion of the external wound. The needle should be full curved with a blunt edge, and it should be introduced so as to take up a fair amount of the kidney substance. It should be introduced very carefully, as the kidney substance is very soft and brittle, and easily torn; the silk suture should be drawn carefully after the needle, and without any tension on the kidney, for it is easily torn through the included portion of the organ.

Sutures should be placed, at least, at the upper and lower ends of the opening in the capsule, and a third or fourth one may be applied near its center. When these sutures are satisfactorily in place, the external wound should be closed, as has already been explained and illustrated, ex-

cept that a narrow strip of iodoform gauze is to be placed in the centre of the wound, reaching from the exposed surface of the kidney to the outer surface of the body. This strip of gauze is left in position for some time, and is said to answer the excellent purpose of establishing a band of cicatricial tissue from the surface of the kidney to the outer surface of the wound, permanent in character, which acts powerfully in fixing the organ in position. In one case in which I adopted this plan, there remains in the centre of the scar a deep depression, which draws the skin inwards, and is no doubt produced by the cicatricial track left by the gauze used in this way.

The external dressings, the same as those applied in the case before you to-day, are designed to keep the wound perfectly aseptic until the healing process is complete.

The wound-stitches can be removed at the end of the week, when, if the case has followed a course free from infection, the wound will be found united. The deep stitches have given rise to no trouble in the cases operated upon by myself, and are left to take care of themselves.

The patient should be confined to the recumbent position for several weeks, so as not to interfere by dragging upon the newly formed and easily torn adhesions.

Some surgeons claim that they are able to control all the symptoms incidental to the presence of a movable kidney, without operation, by a properly fitting pad applied to the abdominal wall against the organ, after returning it to its normal situation, and holding the pad in position by a body bandage.

The operation of nephrorrhaphy is not a dangerous one, and further experience with it may give to it a definite and positive position among the surgical operations upon the kidney.

MEDICAL PROGRESS.

Therapeutics and Pharmacology.

SALICYLIC ACID FOR THE PREVENTION OF SCARLET FEVER.—In the *Centralblatt für klinische Medizin*, for October, are quoted by DR. G. STICKER, some of the clinical experiences of Dr. G. de Rosa, an Italian physician, in an effort to curtail an epidemic of scarlet fever by the internal administration of salicylic acid. Out of sixty-six children exposed to infection—twenty-seven patients being down with the disease in the same building—only three contracted the fever, after the salicylic plan of treatment had been put into operation, and in these three cases, the failure was ascribed to the fact that there had probably been a longer exposure to the infection than in the other set of cases. It is recommended that

the drug should be given promptly after there has been danger of infection, the dose being one to five grains daily until the exposure has passed by. Isolation is not regarded as necessary, if all susceptible material shall be brought promptly under the influence of the drug.

KOCH'S TREATMENT OF TUBERCULOSIS: GENERAL EFFECTS.—In a clinical lecture delivered at the Hôpital Laënnec on December 14, PROF. CORNIL (*Semaine Médicale*, December 17) gave the results of further observation of the cases in which he had employed Koch's treatment. With regard to the three patients in whom the first injection had caused albuminuria—in two of them there was then (a fortnight after its first occurrence) no trace of albumen in the urine; the third still showed slight traces thereof, but it is not quite certain that he was entirely free from it before the treatment was begun. In the case of another patient suffering from diabetes and calculous pyelo-nephritis, as well as tolerably advanced phthisis, the urine became rather less purulent after the injection of very small doses. These cases seemed to M. Cornil to show that the renal complications caused by Koch's fluid are merely temporary, and that, even when the kidneys are diseased, the treatment is not absolutely contraindicated, although it must be used with extreme care. With regard to the reaction, Prof. Cornil pointed out that it is a mistake to suppose that after the injection the temperature simply rises to a greater or less height, and then falls to the normal point. In his cases the temperature was taken on the rectum every two or three hours. In one case an injection at 11 A.M. was followed at 7 P.M. by a temperature of 39.4° C. Two hours later it had fallen to 37.4° C., but on the following day, though no further injection had been given, it again rose 39.5° C., afterwards falling gradually and with slight oscillations to normal. The type was that of quotidian fever, lasting two days. In a second case an injection of three milligrams sent the temperature up to 40.8° C. on the second day, to 39° on the third day, and to 39.5° on the fourth, the record being almost normal in the intervals. It was, in fact, an example of intermittent quotidian fever lasting three days. In a third case, that of a child, the injection at first caused a slight fall of temperature, and it was not before the third day that it reached 39.4° , after which defervescence took place gradually. These three patients suffered from circumscribed lupus of the face, and were all in good health, without any abnormality of temperature before the treatment. M. Cornil insists that these irregularities in the course of the reaction should be borne in mind, and that a sufficient interval should always be allowed between the injections so as to avoid any danger of cumulative action. In a patient suffer-

ing from lupus erythematosus the general action was extremely intense, while there was no sign of local reaction. In six patients suffering from syphilitic lesions, inoculated by M. Humbert in the Hôpital du Midi, no reaction took place. M. Cornil then gave a summary of M. Hénocque's spectroscopic examination of the blood (see abstract, p. 98), and expressed the opinion that the amount of oxyhaemoglobin gives a fair measure of the effect of the injections, and adds that it cannot be doubted that where it is diminished the patient's general condition becomes worse, and it may be concluded that the injections are doing harm. While not venturing as yet to pronounce a final judgment on the value of the method, Prof. Cornil says that with proper care there is little risk of doing any harm to patients by the injections; that in certain forms of tuberculosis, notably in lupus, "appreciable improvement" is produced; and therefore a further trial of the treatment is justifiable.—*Brit. Med. Jour.*

HYPNAL.¹—Tersely told, hypnal is the product of combining equal parts of hydrate of chloral and antipyrine. It is an oily liquid of ether odor and chloral taste. Brought out last year in France, by Blainville, it was noted later by Behal and Choay, who found three distinct compounds, one of which was worthless; the others were called monochloral antipyrin and bichloral antipyrin. Reuter, testing one, gave it the dreadful name of mono-tri-chloral acetyl dimethyl-phenyl-parazalone, and declared it inert. He, however, used the non-active product. Dr. Bardet, of the Cochin Hospital, made the first medical experiments, and—Heaven bless him!—called it hypnal. He reported twenty-two cases in which one-gram (fifteen-grain) doses acted well as a sedative, soporific, and anodyne, and especially useful in insomnia due to cough or pain.

Frankel—whose paper in the September number of the *Bulletin gén. de Thérapeutique* is the latest from foreign sources—after thirty-three trials, wrote in its favor. Schmidt commends it; so, too, Quintard.

The consensus of opinion among Continental observers is that hypnal is an efficient sedative, soporific, and analgesic; it is more hypnotic and less depressing than chloral; it is not caustic like chloral nor irritant like antipyrin, and it is more readily taken, being more tasteless than either.

On respiration it is much like chloral; on circulation it is less disturbing than chloral. It is antipyrretic, and non-irritant by mouth, bowel or skin. It is said to be particularly adapted to children, and to patients with phthisis, lessening fever, pain, insomnia, and unrest. Schmidt found that fifteen grains equalled, in sleeping effect, about nine grains of chloral.

¹ Selections from a paper read before the Medical Society of the County of Kings, by J. B. Mattison.

The dose named by writers noted is fifteen to thirty grains. I have given fifteen to sixty by month, double if by bowel, and fifteen hypodermically. It can be given in capsule or solution preferably the former. If the latter, twice the amount of alcohol should be added to the elixir of syrup. By bowel, in gum arabic. Subcutaneously, direct. Convenient formulæ:

R—Hypnal, ℥ xv.

Alcohol, ℥ lx.

Elixir or syrup, ad ℥ cxxl.

M. Sig.: One dose; one-third tumbler water after.

R—Hypnal, ℥ xxx.

Mucilag. acaciae., ʒ j.

M. Sig.: One injection.

R—Hypnal, ℥ xv.

M. Sig.: One dose, hypodermically.

—*Medical Record.*

RESORCIN IN DIPHtheria.—ANDEER has recently collected evidence in regard to the usefulness of resorcin as an antiseptic, and especially with reference to its employment in diphtheria.

Recent investigations have shown that this drug is a very active antiseptic, and harmless even in solutions containing 10 per cent. of it. A 10 per cent. solution in glycerine penetrates the tissues rapidly. At the St. Lazare Hospital it has proved serviceable in diphtheria.

It should be used every one or two hours, day and night, locally to the diseased spot. A spray of a 5 per cent. solution should be kept up in the patient's room, and further, two to four teaspoonfuls of a 2 per cent. solution of resorcin in syr. terebinth. should be administered daily.

In diphtheria of the larynx resorcin is of little value.—*Centralblatt f. d. gesamte Therapie*, Heft. 9, 1890.—*Am. Jour. Med. Science.*

Medicine.

THE EFFECTS OF EXTIRPATION OF THE PANCREAS.—DR. BOCCARDI, of Naples, remarking that, though a good many researches have been published by various observers of experiments in which the pancreas has been removed with the result of producing glycosuria, no detailed account of the pathological condition of the tissues and organs had appeared, determined to remedy this defect in our knowledge, and undertook a new research on the subject in the anatomical institute of the Naples University. A preliminary note has just been published by him in the *Riforma Medica*, in which he describes the anatomical appearances in animals after deprivation of the organ in question. All or nearly all were greatly emaciated, notwithstanding plenty of nutritious food after the operation. No boils or other cutaneous affections were found. There were no morbid changes in the salivary glands, nor in the esophageal and buccal glands, nor were there any modifications in the conditions of renewal of the glandular elements. There was

little or no change in the stomach. Brunner's glands were always normal, but Lieberkuhn's glands in many cases presented an increase in the karyokinetic changes of their epithelium; sometimes the epithelium was much enlarged and altered, goblet cells being only discoverable at rare intervals, and the whole had somewhat the appearance of Brunner's glands. There were practically no changes in the œsophagus or in the nervous elements in the coats of the digestive tract. The liver always presented morbid changes, even in a dog which had been operated on only four days before it was killed, and had only just begun to pass sugar in the urine. Most frequently these were fatty degeneration and simple atrophy; sometimes also there was a vacuolar condition of the cellular protoplasm, ending in complete destruction of the cells. The hepatic blood-vessels were frequently distended and filled with blood, and sometimes small hæmorrhagic spots were seen. The spleen, thyroid, and suprarenal capsules did not present any definite morbid changes. In the kidneys only slight and occasional changes were found. There was never any glycogenic infiltration of the epithelium; this condition also was entirely or almost entirely absent in the liver. Herein Dr. Boccardi believes the main distinction lies between natural and artificial diabetes. The cardiac plexus was normal. In six out of twelve cases examined there was atrophic degeneration of the pyramidal tracts of the spinal cord, most marked in the neighborhood of the cervical enlargement. No neuritis or degeneration was found in the splanchnics or pneumogastrics, or in the anterior and posterior roots. In one case only was any morbid change detected in the sciatic nerve. No important change was found in the brain or medulla, or in the muscular system. It would thus seem that various lesions are produced in a short time after the extirpation of the pancreas. The state of the spinal cord would appear to be of special interest in the light of Charcot's recent researches.—*Lancet.*

POINTS TO BE OBSERVED BY ELDERLY MALES.

—DR. R. HARRISON offers the following advice to elderly men: 1. To avoid being placed under circumstances when the bladder cannot be emptied at will. Nothing is so bad for a large prostate, though it may be working satisfactorily, as an enforced retention. It is often the first cause of a permanent atony. 2. To avoid checking perspiration by exposure to cold, and thus throwing additional work on the kidneys. In climates like our own, elderly persons should, both in summer and winter, wear flannel next the skin. 3. To be sparing of those wines and spirits (if used at all) exercising a marked diuretic effect either by their quantity or quality; select those which promote digestion without

palpably affecting the urinary organs. A glass of hot gin and water, or a potent dose of sweet spirit of nitre, will not do anything to remove the residual urine behind an enlarged prostate. 4. To be tolerably constant in the quantity of fluids daily consumed. As we grow older our urinary organs become less capable of adapting themselves to extreme variations in excretion. Therefore it is desirable to keep to that average daily consumption of fluids which experience shows to be sufficient and necessary. How often has some festive occasion, where the average quantity of fluid daily consumed has been largely exceeded, led to the over-distention of bladder long hovering between competency and incompetency. The retention thus occasioned by suspending the power of the bladder, has frequently been the first direct step toward establishing a permanent, if not a fatal, condition of atony or paralysis of this organ. 5. It is important that from time to time the reaction of the urine should be noted. When it becomes alkaline or offensive, the use of the catheter may be necessary. When a catheter is required it is most important that its selection should not be left entirely to the instrument-maker. There are other points to be considered beyond the fact that it is to serve as an artificial outlet for the urine from the bladder. An unsuitable catheter in a prostatic case may do much permanent harm. 6. Some regularity as to the time of performing micturition should be inculcated. We recognize the importance of this in securing a regular and healthy action of the bowels, and though the conditions are not precisely analogous, yet a corresponding advantage will be derived from carrying out the same principle in regard to micturition.—*Medical Press and Circular*.

Biology.

ANTAGONISM BETWEEN BACILLI OF ANTHRAX AND "BLUE PUS."—DR. N. BLAGOVESTCHENSKY (*Annales de l'Institut Pasteur*, Tome iv, No. 2, November, 1890), gives an account of some experiments of which the following are the most important results: Simultaneous inoculations into the anterior chamber of the eye of the rabbit with the bacillus pyocyaneus and anthrax bacillus are accompanied by a destruction of the latter, the animal not succumbing to anthrax. Such inoculation does not, however, except in very rare cases, render the animal immune from a later attack of anthrax. If the bacillus pyocyaneus and the anthrax bacillus are not inoculated at the same point the effect of the pyocyaneus bacillus is less marked, and more of the animals die from anthrax. When anthrax spores are introduced along with the blue pus bacillus their development is interfered with. As the result of many experiments the author concludes that the sterilized products of the blue pus bacillus can, as

Woodhead and Cartwright Wood pointed out, influence to a certain degree the development of the anthrax bacilli, but that it requires a considerable quantity to effect this result, as where the inoculations were made into the eye simply, the quantity of blue pus products was small and many of the animals succumbed to anthrax. He also shows that even outside an animal the blue pus bacilli exercise a very marked inhibitory action on the development of anthrax bacilli, and he explains the fact that his experiments do not agree with Freudenreich's by the assumption that Freudenreich was working with cultivations of too great an age, as exceedingly young cultivations and very old ones—more than five weeks—appear to have little retarding effect on the development of spores or on the growth of bacilli. From other experiments that he made in moist chambers, he is convinced that the substance that inhibits the action of the bacillus is a volatile substance that readily escapes on exposure to air. He gives full descriptions of sixty-seven most careful experiments, all of which were made under Metchnikoff's guidance and advice.—*Brit. Med. Jour.*

ACTION OF LIVING BLOOD ON BACTERIA.—PROF. BONOME has recorded the results of his researches on the following points: Whether physiological alterations in the blood play any part in modifying its destructive action on bacteria; whether it is possible to produce alterations in the composition of the blood of such a nature that the normal inimical action against bacteria may be altered; and whether it is possible to derive any reliable data that will throw light on the subject of immunity. As a result of his experiments he comes to the conclusion that staphylococci introduced directly into the blood are destroyed in from ten to twenty-five minutes; more rapidly in the blood of young rabbits than in older animals of the same species. He then, by injecting the poison obtained from the pus of an old empyema or a chronic abscess in small quantities into healthy rabbits, proved that the bacteria-destruoying activity of the blood is increased, the organisms used being staphylococcus aureus, albus and citreus. He holds, however, that the introduction of such poison does not appear to exert any influence upon the similar activity of the fixed tissues. Poison from acute pus obtained in a similar manner appears to exert not the slightest influence on the destructive action of the blood; while, owing to its effect upon the tissue-elements, it diminishes their power of destroying such organisms as the staphylococci above mentioned. Similar poison from pyogenic staphylococcus cultures does not increase this destructive power of the blood against the above-mentioned organisms, and any immunity that is produced depends not on the rapidity and certainty with which the blood destroys the organisms introduced into its stream, but

rather upon a greater resistance which the tissue elements exert against the bacteria poison, when they have become accustomed to the action of the poison by remaining in contact with the metabolic products of the same bacteria. He also gives experiments to show that water injected into the veins can diminish this destructive activity of the blood to a certain extent, but never completely; for, although the animals so injected and control animals died about the same time, those in which water had been injected usually showed small purulent deposits in the kidneys and myocardium, and more or less fatty degeneration of the epithelium of the kidneys, so that he considers that, in addition to this slight diminution in the destructive activity of the blood, there is some alteration of the protoplasm of the cells, probably due to the absence of salts and the cutting off of the full oxygen supply by the presence of water, by which their resistance is considerably diminished in certain areas, and owing to which they are more readily attacked by the injected staphylococci.—*Brit. Med. Jour.*

Bacteriology.

EFFECT OF HIGH TEMPERATURE ON THE TYPHOID BACILLUS.—DR. JANOWSKI (*Centralbl. f. Bakt. u. Parasitenk.*, Bd. viii, Nos. 14 and 15, 1890) in the course of his experiments on the action of high temperature on the typhoid bacillus, says that, with the exception of Sternberg's experiments, there are none that can be taken as entirely satisfactory, the results being vitiated by more or less imperfect methods. By the use, however, of a double-walled vessel, the inner chamber containing water, the outer a layer of hot air, and the outer wall surrounded by felt, except where the Bunsen is applied to heat the air, he obtained a vessel in which the radiation and conduction were so equalized that the water remained at the same temperature throughout for a considerable length of time. By placing test tubes within this chamber, and heating the gelatine contained in them to a required height before introducing the material to be tested, he was able to get extremely satisfactory results. Using typhoid bacilli grown for three days on gelatine, or from four to five days on potatoes (so that spores might be present), he exposed these to various temperatures, ranging from 40° up to 80° C., for periods of from five to ten minutes, and then made "tube-plate" cultivations according to Esmarch's method. Down to 55° C., when exposed for ten minutes, the cultivations were always sterile—that is, the bacilli had been destroyed, but 55° C. for five minutes was not sufficient to prevent their germination when again placed under favorable conditions. In only one case, after an exposure to 56° C. for ten minutes, were three colonies developed. In all other cases complete destruction of the typhoid bacillus was

obtained at this point, and he therefore looks upon 56° C. as the temperature fatal to its development. In this, his experiments agree with Sternberg's. As regards low temperatures, from a large number of experiments that he made on typhoid bacilli, both by submitting these to natural and artificial cold, in broth, and dry on threads, he came to the conclusion that, although the results vary somewhat in different cases, according to the conditions in which the bacillus exists during the period that it is exposed to the cold, the extreme degree of cold, especially when continued for some time, or where frequently repeated, has a markedly injurious effect upon the vitality of the typhoid bacillus, a temperature of -14° C. being sufficient completely to destroy the bacillus in a fluid medium. In the dry condition this does not always hold good.—*Brit. Med. Jour.*

Otology.

MICROBES IN OTITIS MEDIA.—DRS. A. MAGGIORA and G. GRADENIGO (*Centralbl. für Bakt. u. Parasitenk.*, Band viii, No. 19, October 30, 1890), mention the results of researches of previous authors, and then give their own methods of examination. They find that by covering and plugging the end of a silver sterilized Eustachian catheter, it may be passed into the Eustachian tube, without becoming contaminated by the nasal mucus. The plug is withdrawn by means of a thread, and a celluloid bougie—which had been sterilized by repeated energetic rubbing with sterilized cotton wool—is introduced for at least 1 centimetre into the tube. The bougie is withdrawn, and then placed in tubes containing gelatine and agar, and plate cultivations are prepared in the ordinary manner. In thirteen cases of chronic middle ear catarrhal inflammation with thickened membrane, fifteen ears were examined with the following results: *Micrococcus caudicans* was found in six out of the fifteen cultivations; *saccharomyces roseus* in four; *saccharomyces ellipsoideus*, *bacillus subtilis*, *micrococcus cereus albus*, *penicillium glaucum*, and *diplococcus citreus conglomeratus* in two each; *sarcina lutea*, *micrococcus citreus* (II), *bacillus albus*, *micrococcus cereus flavus*, *sarcina alba*, *merismopedia aurantiaea*, and *micrococcus opalescens* in one each. In one case nothing was found, and in one non-pathogenic organisms that liquefied gelatine were met with. The authors conclude that in the later chronic or dry stages of middle ear inflammation there is no evidence of the presence of pathogenic organisms, as all those mentioned above may be looked upon as entirely innocuous. As regards the earlier stages, although there is nothing proved as yet, they consider it is quite possible that specific infective organisms may play some part, as their experiments are not at all inconsistent with such a condition.—*Brit. Med. Jour.*

THE TREATMENT OF ACUTE ANÆMIA.

So plainly indicated a procedure as transfusion of blood would not be neglected were it not for the dangers which attend its execution. These dangers have again and again been illustrated in the practice of every advocate of direct transfusion, and the most enthusiastic of them have been compelled to abandon the method and substitute defibrinated blood or the injection or infusion of artificial solutions. So dramatic a procedure as direct transfusion of blood appeals to the common mind, and it is not wonderful that it has been urged and even practiced not only for acute traumatic anæmia, but for pernicious anæmia, for chlorosis, for the anæmia of the chronic infectious diseases, and for sepsis and old age.

Death in acute anæmia is due to an anæmia of the brain. This, in turn, may be the result either of failure of the heart to propel the properly oxygenated and nutrient blood to the brain centres, or to the deficient quality of the fluid still properly supplied. The heart itself is able to beat for some time after its nutrition has been wholly shut off. The failure of this organ in sudden loss of blood is due to the inadequate filling of its cavities, and the resulting mechanical incompetency of the motor apparatus of the heart. Thus we conceive the possibility of two forms of anæmia of the brain, the one quantitative, the other qualitative.

The blood and the lymph are found in the body in nearly equal proportions. Whenever there is a deficiency in one of these fluids that deficiency

is supplied from the other. The rapidity with which the loss of a small quantity of blood is restored has often been noticed. Even in twenty minutes after the loss of 10 per centum of the entire bulk of the blood, the arterial tension will have in this way nearly regained itself. Not so the quality. MICULICZ (1890) has shown by clinical experiment and observation that in the otherwise healthy the hemoglobin, and presumably the corpuscles, are restored in a loss of 5 per centum of the blood, only after five days. An additional five days is required to repair the loss of each further twentieth. In his experiments on animals, ROSENBERG¹ found that a rapid loss of two-fifths the total quantity of the blood was usually borne; the loss of more than two-fifths and less than one-half was sometimes fatal, while the loss of more than one-half the blood was invariably followed by death. He also found that the subcutaneous infusion of a 0.6 per cent. salt solution temporarily resuscitated animals that had suffered a loss of more than one-half the total quantity of their blood, but that they invariably perished subsequently in spite of the infusion. This is certainly all very significant. HUNTER² has shown us the fate of intra-peritoneal injections of blood. Following such an injection the intravascular blood becomes rapidly concentrated from the effusion of serum into the injected blood, this is some hours later followed by the restoration of the circulating blood to its normal quantity and concentration, and still later by the slow migrations into the circulation of the injected blood. Its presence may be noticed for several days by the increased number of corpuscles.

The first indications, then, in severe acute anæmia is to fill the blood-vessels in the three vital parts, the brain, the heart and the lungs, by maintaining the most favorable position of the body of the patient. The same result may be attained more tardily, though more conveniently, by temporarily shutting off from the circulation the larger extremities and the abdomen by means of the elastic bandage. These two procedures have been termed autotransfusion.

When the anæmia is so excessive that autotransfusion is inadequate to restore the mechanical necessities of the circulation the anæmia is fatal, but autotransfusion may temporarily re-

¹ Virchow & Archiv. Bd. cxvii
² Journal of Anatomy 25.

store the functions of the heart and fail to meet the needs of life. Then there is but one source of relief. This is to be found in the lymph. The rapidity with which the blood pressure is raised is remarkable. It is usually complete at the end of an hour or two. Therefore, when the symptoms of a low blood pressure remain after this time and the mechanical necessities of the circulation are unmet, washing out the remaining lymph by means of a subcutaneous infusion of a neutral salt solution meets the indication of the case. The amount of salt solution as well as its concentration need not be very exact nor need the temperature to be so well regulated as in infusion directly into a vein, for the tissues act as a sort of a ballast and reduce the infusion to a proper concentration and temperature. They retain also any excess in the quantity of the infusion until the blood pressure is reduced again by excretion.

After the mechanical needs of the circulation are met the quality of the blood may be so impaired that a vital equilibrium cannot be attained, and the patient sinks into a state of rapid dissolution. For such severe anemias the infusion of the salt solution should be followed by the injection of blood or by the transfusion of defibrinated blood.

THE ETIOLOGY OF TUBERCULOSIS.

Some important researches on this subject have been published in the *Medical Record* by Dr. H. P. LOOMIS, of New York. Starting from the well-known fact that tubercular deposits are sometimes found in the bronchial glands of persons who give no evidences of tuberculosis of other organs, and that, in some cases of pulmonary consumption, tubercles of apparently older date in the bronchial glands seem to have been the starting point of the infection, he undertook to determine in how large a proportion of persons who were free from visceral tuberculosis the bronchial glands contained the infecting element. For this purpose he tested the bronchial glands of forty-eight persons, dying from accident or acute disease, by triturating the glands, with due precautions against contamination, in distilled water, and injecting the mixture into the pleure of rabbits. The rabbits were killed after the lapse of a sufficient time, and, in case of their presenting the

appearances of tuberculosis, the nature of the lesions was still further tested by inoculating other rabbits from them in the same manner. Only in case of the success of inoculations of this second series was it assumed that the glands used for the first inoculation were tuberculous. In none of the cases used for inoculation were tubercles found in any other organs than the bronchial glands. In several of them the macroscopic appearances of glandular tubercles were found; some of these, however, gave negative results by inoculation. In a few, the tubercle bacillus was found in the tissue by microscopical examination.

Eighteen of the rabbits inoculated died too soon to determine as to the success of the inoculation. Of the remaining thirty, eight developed the lesions of tuberculosis, the character of which was confirmed by the success of inoculations on other rabbits. Three others caused lesions so strongly resembling tuberculosis that secondary inoculation was required to determine their non-tubercular nature. In five of the successful cases, death occurred suddenly from accident, while the persons were in apparent health.

The material for the experiments was mostly taken from hospital patients, and the author suggests that they are probably more exposed to infection than persons living in more favorable hygienic surroundings.

Two of the cases were of special interest. One was that of a prize-fighter, who had come to New York to give exhibitions, and died of pneumonia on the seventh day of the disease. At the autopsy, all of the organs were found normal, except the lower lobe of the left lung, which presented the lesions of the second stage of lobar pneumonia, and an enlarged bronchial gland. The other was a woman 70 years of age, who had been, for more than a year, a helper in the wards of Bellevue Hospital, where there were many tuberculous patients, and had always seemed to enjoy good health apart from the infirmity incident to her age. She died suddenly, from apoplexy, and at the post-mortem examination the lungs were found entirely normal, with the exception of abundant pigment. One bronchial gland was much enlarged. In both cases the animals inoculated developed the lesions of tuberculosis, in the latter, of a very virulent character.

In three of the cases giving negative results, calcareous nodules, and in two others cheesy

masses, presenting to the naked-eye appearances of tubercle, were found in bronchial glands. The failure of the inoculation experiments in these cases was thought to show the death of the bacilli, in case they had ever been present.

These experiments seem to show that it is possible for the infection of tubercle to remain latent in the bronchial glands for an indefinite length of time, and, on the other hand, probable that, after a long period of latency, it may enter into the circulation and infect vital organs. The thought that any of us may be carrying around in our bodies the germs of such a disease is not exactly a cheering one, although it is not probable that the knowledge adds anything to the risk in a given case, and it is open to every one to hope that even if such is the case, he may be one of the lucky ones in whom it is destined to go no farther.

BERI-BERI IN THE GRAND BANKS FISHING FLEET.

DR. W. S. BIRGE, of Provincetown, Mass., has written to the *Boston Medical and Surgical Journal* a brief note regarding the occurrence, during the past two years, of cases of beri-beri among the fishermen of the fleet sailing from his town to the Grand Banks. In the Autumn of 1889, he was called upon to attend seven cases, coming from two different vessels, which have the interest of rarity in that these cases originated in a quarter of the globe where the disease has not been supposed to exist. In October, 1890, also, as many as twenty cases have been landed at Provincetown from vessels arriving from the Grand Banks, eleven cases occurring on one vessel, out of a crew of thirteen. Two of these cases died within twenty-eight hours after having been brought ashore. Some of the cases have been received at the United States Marine-Hospital at Chelsea, while others were treated at their homes. The symptomatology is described as quite uniform in this series of cases, the prominent signs being general cedema, shortness of breath with precordial distress, numbness of the lower limbs, shuffling gait with decided inability to lift the leg at the knee. Only one case was confined to his bed, hydrothorax having supervened upon the general cedema. This man died, five days after his re-

turn home, with the symptoms of heart failure and pulmonary cedema. The other cases, after a period of two to six weeks, recovered. It was reported that a case had died on the voyage home, the symptoms of which were described as similar to the one above referred to as fatal. Albuminuria was present in only one case and there was some doubt if that was properly attributable to this disease. The spleen was greatly enlarged in three cases and the bowels in all were constipated, but probably not more so than might be expected among men who go fishing to the Grand Banks, a condition that no doubt results from the kind of food furnished on such voyages and a very general neglect among the fishermen to attend the functions of their bowels. The digestive organs seemed to be but little affected by the disease, the appetite being fairly good in nearly all the cases; one case only presented the symptoms of nausea and vomiting. The temperature was normal in all the cases that subsequently recovered. The knee-jerk was in two cases entirely lost, and in all diminished. There was, as reported by the patients themselves prodromic period marked by depression, muscular weakness and indisposition to work, also, by an cedematous condition of the areolar tissue of the anterior aspect of the legs; some cases had severe cramps and pains of a neuralgic character. The apparent cause for all these cases was defective food-supply. In the case of two vessels it was found out that they had been poorly fitted for the voyage; the two previous years had not been prosperous ones to their owners so that the outfit was cut down in every possible way: the salt beef was of a poorer quality than usual and the supply of fresh vegetables was very meagre. The catch of fish was at irregular intervals, so that the possession of this article of diet, in a fresh state, was not a frequent occurrence. The majority of the cases, in which the disease occurred, were strong, able-bodied men, in whom there were no recognizable traces of constitutional impairment. The treatment was almost wholly limited to a dietary management in which the chief ingredients were the coarsely prepared grains as oat meal and wheaten meal, along with a liberal allowance of fresh beef, diuretics and hydrogogue cathartics were used in some cases where the cedema was most marked.

EDITORIAL NOTES.

THE SECRETARY OF THE SECTION OF SURGERY AND ANATOMY of the American Medical Association is Dr. W. E. B. Davis, of Birmingham, Ala., not Dr. John B. Deaver, of Philadelphia, as erroneously announced.

ELECTRO-THERAPEUTIC ASSOCIATION.—A convention of American Physicians interested in electro-therapeutics has been called to meet at the Academy of Medicine, No. 17 West 43d Street, New York, on the 22d inst., at 11 A.M., for the purpose of organizing an American Electro-therapeutical Association. A general attendance of those interested is invited.

THE OHIO MEDICAL UNIVERSITY.—This is the name of a new institution that has recently been incorporated in Ohio, and which is to be located at Columbus, the thriving Capital of that State. The new University will consist in a Department of Medicine and Surgery, a Department each of Dentistry, Pharmacy, Midwifery, and a Training School for Nurses; and will be supplemented by a large new hospital, the gift of a number of the wealthy, philanthropic protestants of that city, and which is said, will cost about \$200,000, when completed.

The incorporators of this new school are: Mr. George M. Peters, a prominent millionaire; Mr. William M. Mutchmore, an influential druggist; Dr. J. F. Baldwin, Editor of the *Columbus Medical Journal*; Dr. John W. Wright, Oculist for the Columbus, Hocking Valley & Toledo, and B & O. Railroads; Dr. R. Harvey Reed, Treasurer of the National Association of Railway Surgeons, Mansfield, O.; Dr. A. E. Evans, Surgeon of the C. C. C. & St. L. R. R., Columbus; Dr. A. F. Enninger, a prominent dentist of Columbus, and Dr. S. L. McCurdy, Surgeon of the Pa. R. R., Dennison, O. One of the prominent features of the new University will be the abandoning of the old-fashioned system of instruction by lectures, and adopting, instead, the "new plan" of "class teaching" similar to the methods now employed in the literary colleges. A graded course of three years of nine months each is to be adopted, which will include daily examinations and grading of the students, thus doing away with the necessity of a final examination.

This new method of teaching medicine, and

allied sciences, has been agitated for years in a majority of the leading medical journals of this country and Europe, but we believe this is the first school to organize on the new plan. It is expected to have every thing in readiness to open the new University about the first of October next.

A LARGE PRIZE.—The Academy of Medicine of Turin has just offered a prize of 18,000 francs for the best work on the "Nature and Prophylaxis of the Infectious Diseases of Man." Essays must be in Latin, French or Italian.

DR. W. W. DAWSON, the eminent surgeon of Cincinnati, ex-President of the American Medical Association, recently expressed a thought in a most terse and pointed way which is worthy of preservation. He said: "Anæsthetics are as essential to surgery as the knife. Both are dangerous, but neither can be ruled out in consequence of their danger."—*Ex.*

LADY DUFFERIN ZENANA HOSPITAL, CALCUTTA.—The building of the Lady Dufferin Zenana Hospital at Calcutta is now making satisfactory progress. The main hospital of two stories will contain thirty-six beds, there being separate wards for Hindus and Mohammedans. A ward will also be set apart for children, and a sum of Rs. 25,000 has already been subscribed for its support. Synd Mehdi Hussein Khan, of Patna, recently gave Rs. 1,000 in aid of the building fund of the hospital, but at least Rs. 20,000 is still required to complete the work.

A REPORT recently issued by the Pennsylvania Board of Health shows that there are 8,318 registered medical practitioners in that State, of whom 641 are of foreign birth, every nation except Spain being represented in the list.

ACCORDING to an American missionary, Bombay is a promising field for dentists, especially if they be of his own nationality. There is, he says, only one good dentist in the city, and he charges \$7.50 for drawing a tooth.

ONEROUS RESTRICTIONS ON MEDICAL PRACTICE IN CERTAIN STATES.—A recent law of New Jersey prohibits physicians from other States practicing their profession within that State's limits. A large number of New York medical men have thus been cut off from their fields of practice at the various sea-side resorts so much frequented

by the citizens of New York during the summer season. It is reported that the Long Branch local physicians were the originators of this piece of legislation. In some other States laws have, within the past few years, been adopted which seem to place somewhat odious restrictions upon the practice of even the most worthy and eminent members of the profession. It is stated that in New York State a physician who was regularly licensed to practice in Brooklyn was arrested in one of the towns of the northern part of the State for giving medical advice to some one whom he met while traveling, when his name was not duly registered with the county officers of the particular county through which he was then journeying.

MEDICAL ITEMS.

THE LEPROSY COMMISSION IN INDIA.—From Calcutta it is reported that the Leprosy Commission has examined many cases at Hyderabad, and it is stated that a few of them were declared to be unequivocal examples of leprosy. It is understood that the commission, after spending six months inspecting cases in the plains, will pass six months at Simla carrying out experiments in connection with the cultivation of the leprosy bacillus.

OWING to the cholera scare in Egypt, the Khedive has by special decree granted a free pardon to all prisoners undergoing sentences not exceeding three months. This means the liberation of about two thousand prisoners throughout Egypt. More than 350 prisoners have already been set at liberty in Cairo.

THE SENATE of Calcutta University has adopted a resolution to make the University a teaching as well as an examining body by adding certain professorships. The scheme has been forwarded to the Government for its favorable consideration.

By decree dated December 4, Dr. Giulio Bizzozzero, Professor of General Pathology in the University of Turin, and Dr. Ottavio Morisani, Professor of Obstetrics in the University of Naples, were named Senators of the Kingdom of Italy.

PROFESSOR SONNENBURG has begun the surgical treatment of pulmonary cavities in the Section for Tuberculosis in the Moabit Hospital at Berlin, and has already operated on four pa-

tients in the presence of Professor Koch. All the cases are said to be doing well.

IN order that the changes produced in tuberculous tissues by Koch's fluid may be determined as accurately as possible, the directors of the Charité Hospital at Berlin have given orders that the bodies of any patients who may die after having been treated by the new method shall be examined as soon after death as the law permits. Koch found such early examinations a great help in his investigations on cholera.

DR. A. F. HOLT, Surgeon-General of Massachusetts, died December 28, in Martin, Fla. Dr. Holt resided at Cambridge, Mass., and left for the South about a month ago for the benefit of his health, he being a sufferer from Bright's disease. He was born in Lyndeborough, N. H., December 16, 1838. He obtained his medical education at the Harvard Medical School and University of Vermont, and served with distinction during the war as hospital surgeon. In January, 1884, he was appointed Surgeon-General of Massachusetts.

CHOLERA IN JAPAN.—The epidemic of cholera which is at present raging in Japan is one of extraordinary severity. It is said to have followed an outbreak of influenza which commenced in February last, and reached its climax in April, dying away towards the beginning of summer. As soon as the influenza disappeared, however, cholera seems to have been imported from China, and, as the *Sei-i-Kwai Medical Journal*, of October 25, says, "furiously invaded with tremendous rapidity." The terrible nature of the visitation may be judged from the fact that up to October 2, 33,863 persons had been attacked, of whom 22,560 died. Owing to the vigorous efforts of the sanitary authorities the epidemic is now, according to our contemporary, "rather rapidly fading away."

THE surgical treatment of peritonitis by drainage does not seem to have found so much favor in France as it has in England or in Germany, and the cases which are recorded are not very numerous.

MINKOWSKI'S discovery that extirpation of the pancreas produces glycosuria has suggested to clinical observers the possibility of diseases of the pancreas in man as a cause of diabetes.

TOPICS OF THE WEEK.

PERFECTED OBSTETRICS.

Dr. Alfred L. Carroll, discussing "the influence of a more perfected obstetric science on the biological and social conditions of the race," has some very pertinent observations on the number of cases of "still-births" and the effect of the present conditions of obstetrical science. For instance, he says:

It is to be regretted that the registration of vital statistics is so imperfect in this country as to preclude any attempt to classify by months the mortality under one year; but the data, such as they are, indicate that, in the United States generally, about 25 per cent. of live-born children die during the first twelve-month.

It would not be unreasonable, perhaps, to assume that at least half of the deaths under one month are attributable to accidents in parturition, and that a large residuum of those occurring in the first year has a similar origin; but the admirable reports of Farr may enable us to go a step farther in the field of inference. The death-rate under one year per 10,000 births in England, for the three years ending with 1875, was 1,527. Of these 95 were ascribed to the acute zymoses, 29 to "teething," 171 to diarrhoea, 263 to "lung diseases," 98 to tuberculosis, 128 to prematurity, 267 to "atrophy," 14 to "suffocation," and 251 to convulsions, leaving 211 "not stated." The deaths from prematurity, "atrophy," and convulsions constitute nearly half of the mortality, all of the former and a considerable proportion of the latter two being referable to the time or act of parturition, and some of the pulmonary disorders having their predisposition, if not their origin, in atelectasis at birth. In Farr's March of an English Generation, based on the labor of over thirty years, he computes that the average deaths per million under one year will be 149,493, of which 30,637 will be from diseases of the nervous system, and 21,995 from respiratory maladies. West, taking a wider view of "nervous" disorders, ascribes to these 30.5 per cent. of all the deaths under one year, and to convulsions alone 73.3 per cent. of the "nervous system" mortality—equivalent to 33,421 to the million births. Nor is he any less cogent in his reasoning than in his statistics. The conclusions which he draws respecting the social conditions have the sound of true earnestness which is refreshing. Under this head he says: "As regards social conditions, I have little to say beyond expressing the belief that misery rather than midwifery is responsible for most of the degradation which blots our vaunted civilization. It may be that in some cases such misery is the outcome of physical disability dating from birth or parturition, but in more instances it is the result of acquired vicious habits. Social statistics show that the numbers of murders, suicides, and other kinds of crime bear about the same proportion to population every year; but of the etiology of criminality nothing can be positively affirmed. Even those who dogmatically ascribe all the ill-doings of the world to alcohol have still to find some antecedent factor, and to explain why the vast majority of consumers of alcoholic beverages refrain from crime. Inebriety is often

the excitant, but the predisposition must be sought behind it. "*In vino veritas*" has a wider philosophical meaning than they who quote it ordinarily wot of.

The vexed question of heredity (not so much of disease as of proclivity to disease) has little relation to obstetrics, save as it has led some enthusiasts to imagine an impossible prophylaxis by forbidding the marriage of physically, mentally, or morally unhealthy persons, and in this way diminishing obstetric practice, except in illegitimate births; and it is doubtful if anything but a destructively retrogressive midwifery or an increasing prevalence of oophorectomy can materially reduce hereditary morbidity, since delicate, and especially consumptive, women seem to be more apt to conceive and less likely to miscarry than their more robust sisters. As a "glittering generality" it may be asserted that every obstetric advance which saves mothers from invalidism and children from incapacity for future effort must promote the social condition of the race, but politico-economic rules and the inexorable operation of natural laws will probably always overshadow in this respect the influence of medical science, or even of Congressional legislation.—*Times and Register*.

THE CHOLERA AND THE MECCA PILGRIMS.

A correspondent, writing to a local paper from Jeddah, says: "The epidemic is completely finished. On October 17, thirty days after the occurrence of the last case of cholera, Dr. Vaume allowed free pratique. Almost all the pilgrims have left. I say nearly all, because there always remain a thousand or so of beggars who, having nothing but starvation before them in their own countries, prefer dying in the sacred land, as being so much nearer to the gates of Paradise. Now is the time to make up the accounts of the pilgrimage—to estimate the number of those who have died. In my estimation—and I have formed a very modest one—the deficit among the returning pilgrims must be put down at 35 per cent. In ordinary years, when there is no epidemic, about 20 per cent. die; this year the cholera has added 15 per cent. to the total number of victims. This estimation of 20 per cent. in ordinary years is by no means too high when one considers the great number of old people taking part in the pilgrimage, combined with the fact that the journey from Mecca to Yambo, *via* Madeira, is an excessively trying one, and that all the people who perform it have passed one day at Arafat and three at Monna with heads bare, exposed to an ardent sun. They commence the return journey, consequently, in a worn-out state, and, once started, caravans do not stop for the treatment of sick, and laggards soon die of thirst, or are murdered by the Bedouins. The poor people must keep perpetually moving on; those who cannot keep up are abandoned, and then the vultures take charge of public salubrity. Although one may have seen many such things during a long existence, I doubt if any one could form an idea of the state of affairs during an epidemic at the time of the pilgrimage without being an eye-witness thereof. Thousands of men arrive on camels each morning at the gate of the town; the number of empty saddles is seldom less than 10 per cent. A man dismounts, staggers a few steps,

writes; his limbs contract, and lo! in an hour he is dead. Another drags himself towards the walls so as to die in the shade; but soon appears a citizen who seizes the unfortunate wretch by the foot, and drags him to a distance; were he to die close to the town the smell would be objectionable! As soon as a pilgrim falls sick the passers-by precipitate themselves upon him and relieve him of the belt wherein he carries his little stock of cash, but no one dreams of attempting to afford him relief. It is a disgrace to humanity." This we believe to be substantially correct. It is time that civilized Europe should take steps to put a stop to these atrocities, and at the same time prevent the spread of cholera.—*Brit. Med. Jour.*

THE DISCUSSION OF MEDICAL SUBJECTS IN THE NEWS-PAPER PRESS.

Some medical men, and even some newspapers, seem to be somewhat disturbed by our remarks on the contributions to newspapers on the Koch treatment of tuberculosis. We are not unreasonable or impractical. The etiquette of the profession has good grounds for its existence in reason and in the nature of things. And any departure from it is sure to be followed sooner or later, and generally quickly, by consequences bad for the person violating the rules of professional custom, bad for others who are led to follow an evil example, and bad for the public, who are hopelessly misled by vague newspaper statements of disease and its remedies. In some of our colonies men of high qualifications and good professional history have taken to the most unblushing advertisement of themselves as prodigies of skill for curing all sorts of disorders. In connection with this matter of Koch an Austrian physician is announced in the newspapers as curing consumption by "Dr. Brown-Séguard's fluid" more effectually than Koch. The following is taken from a daily provincial contemporary as a prominent paragraph, and corresponds with an advertisement to a similar effect in another issue of the paper:

"DR. KOCH'S TREATMENT FOR TUBERCULOSIS.—Mr. —, one of the medical staff of the — Hospital, yesterday received a supply of Dr. Koch's fluid, sufficient, we understand, to serve for upwards of five hundred injections. There will be a demonstration of the application of the treatment at the — Hospital on Thursday before a medical audience."

There can be no defence of such communications to newspapers. If the design was to communicate with the profession, the post or the medical journals would have been the proper medium. The most unseemly uses have been made of Dr. Koch's kindness in supplying his fluid. Such things are not only a breach of professional etiquette and tradition, but in the long run the public suffers and suffers most. It is misled. Statements that need checking and correction are put forth with confidence. Every day is showing more clearly what an injustice has been done to Koch by the forced premature disclosure of his great discovery—for great it is, whatever may be the limitations of it. But this is nothing compared with the cruel disappointment created for those who are led to expect more of the discovery than he has ever promised or could promise. This is the kind

of considerations which underlie the etiquette of the profession. We repeat, we are not unreasonable. The magnitude of Koch's expressed hopes may perhaps excuse some haste and premature publicity in newspapers. But they should not be abetted and encouraged by members of a profession who cannot with impunity prescribe through newspapers or adopt them as media for the discussion of the profoundest questions in pathology and therapeutics.—*Lancet.*

ITALIAN HONORS TO GERMAN PHYSICIANS

An Italian correspondent writes: "At the meeting of the Accademia Medica di Roma on the 7th ult., the President, Professor Guido Baccelli, forwarded to Dr. Koch the following telegram, which had been voted with acclamation: 'The Royal Medical Academy of Rome sends to its illustrious Honorary Fellow, Robert Koch, its tribute of applause and admiration for his profoundly scientific and humanitarian discovery.' At the same meeting the Royal Medical Academy, again at the instance of its President, seconded by the acclamation of the assembled associates, set aside *ad hoc* its formal regulations to nominate Rudolf Virchow a 'Socio d'Onore' (Honorary Fellow), and resolved to contribute 500 lire (£20) to the fund for the gold medal which is to be struck for this 'maestro dei maestri' (master of masters) on the approaching completion of his seventieth year."

LITERARY INTELLIGENCE.

It is announced that Professor Mathias Duval will for the future be associated with Dr. G. Pouchet in the editorship of the *Journal de l'Anatomie et de la Physiologie Normales*. This well-known periodical, which was founded by Professor C. Robin, has now entered on its twenty-seventh year, quite a respectable antiquity for a journal of so high—not to say dry—a class which appeals to an audience which must in the nature of things be "few," however "meet."—The *Revue Philosophique*, which now enters on its sixteenth year, is remarkable as being probably the only periodical in the world which can boast of a Minister of Cabinet rank as its editor. M. Ribot, however, is something more than a mere Minister for Foreign Affairs; he is Professor in the Collège de France, and a philosopher of credit and renown, not only among politicians, but among philosophers. A noteworthy feature of the *Revue Philosophique* is the prominence given to such subjects as the nervous system, mental pathology, anthropology, etc. Both the periodicals just mentioned are published by Félix Alcan, who, it may be added, also plays the part of Lucina to the *Revue de Médecine* and the *Revue de Chirurgie*.—On January 1, 1891, will appear the first number of a new journal devoted to stammering and speech affections generally. It is to be entitled *Medicisch-pädagogische Monatsschrift für die Gesamte Sprachheilkunde*, and will be edited by Herr Albert Gutmann, and Dr. Hermann Gutmann, of Berlin.—It is announced that in January, 1891, a new series of the *Journal of Laryngology* will be commenced. Dr. John Macintyre, of Glasgow, will be associated with Dr. Norris Wolfenden in the editorship, and these gentlemen will have "the active aid and co-operation of Drs. Dundas Grant, Barclay J. Baron, Hunter Mackenzie, and Sir Morell Mackenzie" in their labors. The publisher is Mr. F. A. Davis, of Berners Street, W., and Philadelphia.—*Brit. Med. Jour.*

FOREIGN CORRESPONDENCE.

LETTER FROM BERLIN.

(FROM OUR OWN CORRESPONDENT.)

To the Editor:—I have been carefully watching the experiments now being made with Prof. Koch's "Heilmittel gegen Tuberculose" which have drawn so many physicians to Berlin from all parts of the globe, not among the least of these from America. I will endeavor to give you an idea of the action of the lymph and also by a few cases which I have selected from a number as being typical, give you an idea as to what results have been arrived at up to the present time. As you know, according to Prof. Koch's paper in the *Deutsche Med. Wochenschrift* of the 13th of November a dose of 0.25 ccm. of the lymph will cause considerable febrile reaction and symptoms in a healthy person, and a dose of 0.01 ccm. will in some persons produce a slight reaction. In tubercular patients the reaction is as follows: From four to six hours after an injection of a full dose (from 0.0005 to 0.01 ccm. according to age and condition of patient, and inversely to the extent of the tubercular infection) the temperature begins to rise, often accompanied by a chill, reaching its maximum about the tenth or twelfth hour. The temperature usually reaching from 39° C. (102.2° F.) to 40° C. (104° F.), but in some cases it reaches as high as 41° C. (105.8° F.). The height to which the temperature rises seems to be proportional to the extent of the tubercular process, hence great care must be taken regarding the dose when the lungs are involved. In all cases of lupus and other external tubercular affections, the lungs should be carefully examined physically, and the sputum for bacilli. With the rising temperature there is often vomiting and considerable depression, headache, and sometimes unconsciousness. The pulse ranges from 120 to 140, and sometimes as high as 180. After reaching its maximum the fever gradually falls, and in from twenty-four to thirty-six hours that which was induced by the injection disappears entirely. The fever curve with its attendant symptoms strikingly resemble an acute sepsis.

In some cases an eruption appears over the body much like that of scarlatina; this, however, disappears with the fever.

The local reaction is the more striking and remarkable, especially in external tubercular affections, where it can be best studied. Seemingly, and as far as has yet been proven in the great number of patients experimented upon, it only appears in the pathological processes, due to the tubercle bacillus, attacking old cicatrices where long before tubercular glands had been removed, often demonstrating the presence of lupus nodules where they had not previously been observed or

suspected as showing where a tubercular bone process lay latent.

Lupus.—As the temperature rises the lupus patch becomes swollen. In all the cases which I have seen tubercular glands and the like, if present, also become swollen and painful. The lupus takes on a red color which deepens with the rising temperature until it is of an erysipelatous hue. From the nodules rays of redness go out into the surrounding tissue, and about the entire patch a light line of anæmic skin forms a line of demarkation between the healthy and diseased tissue. On the surface of the lupus small vesicles form, from which a light colored serum exudes, at times tinged with blood; this forms a thin crust which in from twelve to thirty-eight hours begins to scale off, leaving under them what seems to be a fine delicate skin. This reaction takes place after each injection, but, as a rule, to a less degree each time, though the dose be increased. One case of lupus of the nose and face which I have in mind was still reacting after the fifteenth dose. In this patient the diseased patch looked much improved though not yet free from its pathological condition. From its looks I think it may possibly be well before very long. A great number of similar cases may be seen in the wards.

Coxitis.—The local reaction manifests itself in a swelling about the affected joint which becomes exceedingly painful to movement or to the touch.

The following two cases of coxitis have ceased to react to ordinary doses of the lymph:

Case 1.—Willie Z., æt. 3 years, coxitis (left). Reaction set in on an injection of 0.0001 ccm. (or 0.1 ccm. of the 1 per cent. solution which is used). Reaction slight on tenth dose of 0.005 ccm.; did not react on eleventh dose of 0.005 ccm., nor on twelfth dose of 0.01 ccm. At the time of the first injection (November 6) the joint was very painful both to palpation and to movement, now the child voluntarily moves his limb and would stand upon it were it not in a perverse position (adducted and flexed).

Case 2.—Osker S., æt. 3 years, coxitis (right). Did not react after last four doses. Though the joint is not painful on movement it is still painful to touch and deep fluctuation can be detected.

How much of the improvement in the above two cases is due to the remedy and how much to the quiet rest in bed is a question, perhaps, not easily answered.

Case 3.—C. S., æt. 41 years, tuberculosis of pharynx and of larynx. The patient entered the hospital with large ragged ulcers on both pharynx and larynx, which were at first thought to be syphilitic in their nature, but, on the injection of 0.002 ccm. of the lymph, he reacted both locally and generally, so that the diagnosis of tubercular ulcers was arrived at.

I mention this case more to show what an aid

to diagnosis the lymph may prove to be. Perhaps its main curative effect may be in this early diagnosis, though I must say that it seems to have a curative effect in itself, especially in lupus. Prof. von Bergmann, Prof. Israel, Prof. Gerhardt and many other eminent men in the profession seem to expect great curative results from the remedy. I have seen but one case in which no reaction took place after a number of doses. This was in a case of spondylitis presented by Prof. Jolly. Tubercle bacilli had been demonstrated a few weeks before the injections were made. Prof. Jolly at the same time presented another parallel case; in this both local and general reaction took place after the first injection.

Case 4.—Max B., æt. 19 years, tuberculosis pulmonis. The initial dose was quite small, 0.002 ccm., as it should be in all cases of lung tuberculosis, for in these cases the lymph is a dangerous remedy. The reason is apparent if we but imagine such a local reaction as occurs in a case of lupus taking place in the lungs. From what I have seen in the wards and upon the post-mortem tables I believe that no case of far advanced lung tuberculosis should be treated by this method, at least not until further experiments have exactly defined the danger limit.

In this case the patient feels much better, night sweats diminished, and he has slightly gained in weight.

The above cases were from the wards of Prof. von Bergmann's and Prof. Gerhardt's clinics.

I have seen but three post-mortems, though more have been made. One a case of basilar meningitis. The treatment by Koch's method began very late in the disease. No demonstrable changes were found in the tubercular processes. The second, a case of far advanced lung tuberculosis, the entire upper lobes of both lungs having been involved. No changes due to the lymph could be demonstrated in the tubercular masses. The third, a case also of very far advanced lung tuberculosis. This patient had received but two injections, one of 0.002 and one of 0.003 ccm., the last injection having been given seven days before death. After the second dose the temperature rose and continued at 39° C. until death. In this case the upper lobes were entirely destroyed and the rest of the lungs in a state of caseous pneumonia. In the larynx a small ulcer seemed to be cicatrizing, otherwise no changes due to the lymph injections could be demonstrated in the tubercular processes.

On all sides cases of marked improvement have been reported, but time alone will tell the real value of the remedy. No doubt many important developments will soon follow, and I will endeavor to keep you posted.

I hope that I have not underrated the value of this "great discovery." I have been careful not to overrate it, as is the general tendency at present.

I think this rapidly written letter will give you somewhat of an idea of the state of the experiments and what has been done so far, at least as I see them.

MAURICE I. ROSENTHAL, M.D.

Berlin, Dec. 8, 1890.

Koch's Method in Pulmonary Tuberculosis.

Dr. E. Fletcher Ingals, of Chicago, furnishes the following clinical notes just received from Dr. Corwin, now in Berlin:

December 16, 1890. Charité Hospital, consumptive wards of Dr. Gerhardt. Kaschuer, painter, æt. 24, married, weight 135 lbs., mother and father both died of quick consumption. Patient, as a child, had typhoid, measles, scarlet fever. September last he began to cough, with some expectoration. At end of September had hæmoptysis (half cup). Had night sweats, chills in evening, some fever. Entered hospital October 30. Cough, weakness, chest pains on deep inspiration. Has good physique, dry skin, no gland trouble. Pulse was regular, 72; appetite fair, tongue coated. Physical examination gave: percussion note short at left apex (supra- and infra-clavicular spaces), also behind in supra-spinous fossa of left side. Bronchial breathing in above locality, many moist râles on expiration and posteriorly, from seventh down evident pleuritic friction sounds. Vocal fremitus some weaker. Heart normal. Vital capacity 2,000 cc. (3,500 cc. normal).

November 6. Small ulceration on left arytenoid body noticed.

November 10. Physical signs about same as above, and left lower lobe behind shows signs of receding, catarrhal inflammation, tubercular bacilli quite numerous. From October 31 to November 18 temperature always normal substantially. Physical signs same as November 10, and weight same (126 lbs.).

November 18 received injection of two milligrams (0.002) of lymph, 9 A.M. Temperature gradually rose to 38° C. at 5 P.M., 39° at 6:30, 39.5° at 8:30, 39° at 9:30, 38.3° at 10, gradually falling off in next twenty-four hours to 36.4° on morning of November 20. The signs of first reaction were (injection at 9 A.M.): At 12 M. face became hot and flushed; at 3 P.M., pains in the left tibia and appearance of measly exanthema on face, with itching; 7 P.M., sweating, pulse dicrotic, conjunctiva injected, subjective feeling of heat not so evident, exanthema more marked; 8 P.M., lancinating pain in left apex.

November 20. He feels well, vital capacity 1,800. Received injection three milligrams (.003), no reaction of temperature therefrom; but slight constitutional disturbance, cough increased. Exanthemata became quite marked in evening;

sputum amounted to 40 cc. in twenty-four hours.

November 21. Right arytenoid body shows grayish white discoloration.

November 22. Injected 0.005 (5 mg.), no particular temperature reaction (37°), none of pulse or respiration. Bacilli found in not very large numbers and without morphological change; pains in neck, left side; slight dyspnoea.

November 24. Injection .008 at 9 A.M. (as usual); reaction of temperature 38.5° with slight constitutional disturbance; right arytenoid body but slightly ulcerated; both vocal cords congested; sputum 60 cc.

November 26. Injection 0.010 (10 mg.) 9 A.M.; hardly any temperature reaction, 37.3° ; sputum formerly nummulated and purulent, became mucopurulent, frothy, 30 cc. in amount.

November 27. Exanthema on face very marked in morning; ulceration on right arytenoid body still present; V. C. cords less congested (has receded); sputum 10 cc.

November 28. Injection 0.0150, slight reaction of temperature following (38.4°), slight constitutional disturbance, sputum 40 cc.

November 30. Injection 0.020, reaction slight, 38.2° . In the sixth slide examined (specimen of sputum) only one bacillus tubercle found.

Lung Changes.—Some dulness still present on left side, clavicular region. Bronchial breathing confined to upper part of left, supra-spinous space; mucous râles rare, but heard in fossa infra clavicular, left side.

December 2. Injection .025, 9 A.M., reaction of temperature very slight, 38.1° ; pulse and respiration unchanged, catarrhal condition of larynx greatly receded, ulceration but little evident.

December 3. Anterior pillars of fauces very red, large number of small inflamed patches appear on them (probably herpes?).

December 4. Injection .030, temperature reaction slight; 38.3° in evening; sputum 20 cc., but slight disturbance generally, weight 131 lbs.

December 5. Sputum largely increased, 80 cc.

December 6. Injection .040 (40 mg.) temperature reaction, 38.5° , sputum 40 cc., four slides (specimens) examined for tuberculous bacilli, none found.

December 8. Injection 0.50, reaction of temperature quite marked, sputum 20 cc.

December 10. Injection 0.060, hardly any reaction, 38.8° ; sputum 20 cc. A new appearance of exanthema on face. Ulceration in larynx better, visible again, no bacilli found in the one specimen examined, vital capacity 1,980.

December 12. Injection .070, very typical reaction of temperature, 39.40° , accompanied by night sweats. Dulness at left apex still evident, no longer bronchial breathing, only occasional râles, 20 cc. sputum. Severe headache.

December 14. Injection 0.070, temperature

38.4° in evening; general disturbance very slight.

December 16. Injection .080, temperature in evening, 38.6° . Since December 10, only 10 cc. of sputum per twenty-four hours; catarrhal condition at apex almost gone. Sputum now entirely mucus, only small spot of slight bronchial respiration. No more night sweats. Bacilli could not be found in several specimens examined. Weight, 132 pounds; appetite good. Will report further as the case progresses.

This is but one of very many similar cases which give evidence by disappearance of night sweats and bacilli, purulent sputum and local signs of a constant improvement under Koch's treatment alone, combined with the usual dietary measures and recovery. And when it be remembered that in the past history of Charity hospital's consumptive wards, improvement and recovery have been very rare exceptions, and a gain in weight of five to eight pounds in two weeks never before reported, such cases as the above are the more significant. In two or three instances patients effected with lupus of many years standing have been discharged from Bergmann's clinic cured so far as present appearances go, after a treatment of from three to six months. Like diseased tissue when deep seated, as in the lung, must necessarily take longer for removal when separated by action of the "lymph" as it would seem, so that we may hope for a very fair determination of the pros and cons of this certainly wonderful remedy in the next few months, especially as the number of patients exhibiting all varieties of the disease is enormous in Berlin alone. It is very fortunate, too, that the "lymph" is being tested among Germans on German patients, for certainly America would never allow this amount of experimentation involving death in some instances, without what might become troublesome investigations. But Germans are asking very few questions and the doctors are telling very few lies about the deaths of those few patients fortunate enough to be hastened on a painfully lingering way. The syringe first recommended by Koch has become already obsolete, superseded by the ordinary piston hypodermic. He goes on to say that abscesses have resulted from using these syringes, though never from using the ordinary syringe when it is properly cleansed.

My impressions gained thus far, lead me to believe in the beneficial, if not ultimately curative action of the new remedy, in cases of lupus and those cases of incipient pulmonary disease and of laryngeal involvement where the patient is of fair strength, especially among males. The patient must be able to bear the repeated induced toxæmia (of the lymph) and to throw off the diseased and disintegrated tissue as it is set free. Though the weight of evidence seems to be favorable, untoward results have been not a few among

weak patients, females and those far advanced in the disease.

The following case was of interest as illustrative of the intense reaction manifested at times:

Emilie Richter, æt. 19, seamstress, entered Hospital Charité and examined November 19. Mother died of "pleurisy" (probably tubercular), father from "accident." One healthy brother; three other members of family died of lung trouble. Patient had diphtheria at 16. Menses regular, no childbirth, no abortion. Anæmia for last five years. Felt well till two years ago, when she changed occupation from maid to seamstress. For last year, pains in chest on right side; dry, hacking cough, no expectoration. Ten weeks ago (beginning of September) had "pneumonia," high fever eight days, since then severe cough and expectoration, no hæmoptysis. Night sweats last ten weeks, appetite poor, great general weakness.

Physical Examination.—Suffering expression of face—small woman, weakly. Non-pigmented anæmic skin, not dry. No exanthemata, conjunctiva and lips very anæmic. Glands not enlarged. Left apex two fingers' breadth, right apex one finger's breadth above clavicle. Dulness at right apex down to fourth dorsal vertebra (hence more consolidated on right side), dullness down to second rib (anteriorly), particularly. Bronchial breathing and moist râles on left and dullness over left clavicle. Posteriorly no distinct dullness. Over left spine of scapula very harsh breathing and occasional crackling. Heart normal, except systolic anæmic murmur. Spleen normal, larynx normal. Patient's weight before injection $40\frac{1}{2}$ kilos. Tubercular bacilli in enormous quantities. Hectic fever, generally rising to 38.6° C. in the evening and falling to 37.5° in the morning. From November 20 to 23 lost 2 kilos, in weight (indicating rate of loss).

November 24. .002 (2 mg.) injected at 10 A.M. Temperature 37° C., rose to 39.5° at 6 P.M., 39.1° at 9 P.M., and fell to 37.2° at 6 A.M. During reaction pulse went up from 100 to 120, respiration from 20 to 25. A chill at 5 P.M. (November 24), lancinating pains in right chest, vomiting, nausea, headache and dizziness. Cough not increased, but expectoration doubled.

November 25. Rose to 39° at 6 P.M. without new injection, fell to 36.5° at 9. Respiration and pulse unchanged. Complaints of pain in chest, and arytenoid bodies show slight discoloration.

November 26. Injected .005 at 11 A.M. Temperature at 37° , rises to 40.4° (104.6° F.) at 6 P.M., where it remains for three hours, falling to 38.5° at midnight. Pulse during reaction went up from 100 to 130. Respiration from 22 to 60 at 6 P.M.

Examination of Lungs.—No change in right upper lobe. Posteriorly, left upper lobe now shows very distinct dullness to spine of scapula, with bronchial breathing and numerous metallic

râles. Patient on this day (November 26) had a severe chill from 12:30 to 2 o'clock. From 4 to 5:30 another chill. During reaction no sweat, but great feeling of warmth. Greater tendency to cough, more expectoration, which is more mucus.

November 27. Temperature normal in morning, respiration normal. In evening former hectic, 38.4° . Feels well, but no change in lung.

November 28. Injected .008 at 9 A.M., with normal temperature. 39.4° at 6 P.M.

November 29. No injection; usual hectic in evening, expectoration much increased. At left apex bronchial breathing has given place to harsh vesicular type. Consonant râles no longer heard. Dulness less extensive.

November 30. Injected .010 at 10 A.M. Temperature normal. At 6 P.M. temperature 39.5° , falling to normal at 3 A.M. Repeated examination shows at posterior left apex no bronchial breathing; dulness far less evident.

December 1. Hectic rises in evening to 38.6° .

December 2. .01 (1 centigram) injected at 9:45. Temperature 37° , at 6 P.M. temperature 39.8° . She complains as usual during reaction of headache, nausea and a feeling of great warmth, no sweat, sleeps well.

December 3. Hectic rises to 38.8° at 6 P.M.

December 4. At 12 injected .015. Temperature 38.2° , fever rises up to 40.1° at 6 P.M. Respiration 60 at 9 P.M., temperature and respiration normal at 6 A.M.

December 5. Hectic rises to 39.2° at 6 P.M.

December 6. Injected .015 at 9:30 A.M., temperature, pulse and respiration normal, 6 P.M., temperature 39.5° , slight dyspnoea; 9 P.M., temperature 39.3° , respiration 72, pulse 120. Intense pain in chest, nausea, vomiting, night sweats, cough and expectoration not increased. Morning weakness. Tubercle bacilli very numerous, no lung change to be detected.

December 7. 9 P.M., hectic low again, 38.2° .

December 8. Injected .015. Temperature 38.1° , rises to 39.1° at 6 P.M., respiration to 52, accompanied with chill, night sweats, pain in left shoulder—no lung change.

December 9. Hectic at 6 P.M., 38.7° .

December 10. Injected .015 at 9:30 A.M., at 12 pulse at 40, at 6 P.M. temperature 39.6° , no dyspnoea particularly, though respiration 40.

December 11. Hectic of 39.7° , pulse 125, respiration 42. Dulness increased anteriorly down to third rib on both sides. Tubercular bacilli still present in large numbers.

December 12. 37.2° A.M., 39.2° P.M. Patient complains of little sleep, headache, great weakness. Cough increased. Slight hypostasis in base of left lung, axillary region.

December 13. Temperature 37.6° A.M., 39.2° P.M.

December 14. Temperature 37.2° 6 A.M., 38.6° 12 M., 38° at 3 P.M., and 39.6° at 6 P.M.

December 15. Temperature 38.2° at 6 A.M., 38.8° at 12 M., 39.4° at 6 P.M.

December 16. Temperature 38° at 6 A.M., 39.3° at 9, 38.2° at 12, 40.1° at 3.

December 17. Temperature 37.6° at 6 A.M., 38.2° at 6 P.M.

From December 11 to 16 a cavity has been forming at right apex, of which the high hectic between injections is expressive.

Temperature in these cases taken in axilla, every fifteen minutes.

SPECIAL CORRESPONDENCE.

Shall The Journal be Removed to Washington?

To the Editor:—In my opinion, the idea of removing THE JOURNAL from Chicago should never have been entertained at all, and I believe it is the desire of a majority of the members that it remain where it is. Chicago is near the geographical centre of the United States, is a great medical centre, and, being by far the greatest railroad city in the country, is better able than any other to distribute THE JOURNAL, speedily, in all directions.

If, however, this question is to be acted upon, let us not wait until the next meeting of the Association, and allow it to be decided by a sectional vote, but submit it to the entire membership and allow us all to have a voice in the matter.

I suggest that you inform us, through the columns of THE JOURNAL, at what time the vote will be taken; then send a blank with each copy of one issue of THE JOURNAL, and impress upon the members the importance of filling it *at once*, before it is lost or forgotten, and sending it either to the Secretary of the Association, or to a committee appointed to count the votes.

It seems to me that this is the only just way to settle the matter, for we are all interested, and entitled to a vote, whether we be country doctors in Illinois or Dakota, or city physicians in Philadelphia, New York or Washington.

F. W. DIMMITT, M.D.

Oneida, Ill., January 6, 1891.

To the Editor:—Let THE JOURNAL remain in Chicago.

B. F. HART, M.D.

310 Front St., Marietta, O.

To the Editor:—THE JOURNAL should remain in Chicago:

First. Because Chicago is centrally located for mailing facilities.

Second. Because Chicago will soon be as well supplied with library advantages as any city in the United States.

Third. Because Chicago is nearer the centre of the membership of the American Medical Association, and consequently more in touch with them.

Fourth. We are opposed to moving it to the East from the West.

H. B. TANNER, M.D.

South Kaukauna, Wis., January 9, 1891.

To the Editor:—I am satisfied with our Journal's present location.

CHAS. W. ROOK, M.D.

San Antonio, Tex., January 8, 1891.

To the Editor:—My vote is for THE JOURNAL of the A. M. A. to remain in Chicago, for the simple reason, that said city is near the centre of this "*Great Republic*." Any of the large Western cities would be preferable to the city of Washington, D. C. "Westward the star of empire rolls."

DAVID S. BOOTH, M.D.

321 N. Jackson St., Belleville, Ill., January 9, 1891.

To the Editor:—I say yes. Washington is not a place of common trade or manufacture, as are other cities of our country. It is our capital, with its many attractions, the pride of the American citizen. It should be made the headquarters of the arts and sciences. THE JOURNAL should be placed with the Medical Museum and Library, and all physicians should have pride enough for their profession and country to cheerfully support it, so as to make it the peer in medical literature of the journals of any country.

What THE JOURNAL most needs and should have is the united support of the medical profession.

JOSEPH WAGGONER, M.D.

Ravenna, O.

MISCELLANY.

Official List of Changes in the Stations and Duties of Officers Serving in the Medical Department, U. S. Army, from January 3, 1891, to January 9, 1891.

By direction of the Secretary of War, the following-named medical officers will proceed without delay to Pine Ridge Agency, S. Dak., and report in person to the commanding General, Dept. of the Platte, for duty in the field: Capt. Henry S. Kilbourn, Asst. Surgeon; Capt. Edwin F. Gardner, Asst. Surgeon; Capt. Edward Everts, Asst. Surgeon. Par. 9, S. O. 304, A. G. O., December 30, 1890.

Brigadier General Charles Sutherland, Surgeon General, will, as soon as practicable, repair to this city, and assume the duties of his office. By direction of the Secretary of War. Par. 9, S. O. 2, A. G. O., Washington, January 3, 1891.

Major James P. Kimball, Surgeon, assignment to duty at Ft. Supply, Ind. Ter., in S. O. 132, Dept. of the Missouri, September 24, 1890. By direction of the Secretary of War. Par. 6, S. O. 4, A. G. O., January 6, 1891.

APPOINTMENT.

Col. Charles Sutherland, Surgeon, to be Surgeon General, with the rank of Brigadier General, December 23, 1890. Vice Baxter, deceased.

THE
Journal of the American Medical Association.

EDITED UNDER THE DIRECTION OF THE BOARD OF TRUSTEES.

REPORT ON LAWS REGULATING
MEDICAL PRACTICE.

Read before the American Academy of Medicine at its Fifteenth Annual Meeting, at Philadelphia, December 1, 1890.

BY RICHARD J. DUNGLISON, A.M., M.D.,

OF PHILADELPHIA.

SECRETARY OF THE ACADEMY.

The changes in the laws of medical practice during the interval that has elapsed since the last annual meeting of the Academy at Chicago, have not been numerous or worthy of any lengthy notice. As the committee whose duty it has been to make the usual inquiry from gentlemen in each State familiar with the subject, I submit, with a few preliminary remarks, some brief extracts from the letters of such of my correspondents as have graciously responded. It will be seen that restrictive legislation is progressive and that the various State laws are, as a rule, working harmoniously and satisfactorily to the benefit of the public and the credit of the medical profession which has so zealously and actively interested itself in these statutory enactments for the protection of communities and individuals. It has been stated that nine of the different States of the Union now require an attendance upon three complete courses of lectures and graduation to entitle the holder to practice medicine in their limits. Five out of the above number are Southern States and were among the first to make the requirement of a more thorough medical education.

Dr. John H. Rauch, the efficient secretary of the Illinois State Board of Health, is of the opinion that "the rule of three courses of lectures before graduation is already assured of general observance." Perhaps in the not very distant future we may still further advance to the principles laid down in a statute of Henry VII, of England, which reads as follows: "The practice of the healing art should be limited to those persons that be profound, sad and discreet, groundly-

learned and deeply studied in physick." And yet we are startled occasionally by the retrograde movement visible even in medical teachers of reputable schools, one of which institutions recently made this frank statement in its annual announcement:

Our graduates may not be classed as scientific physicians; they may not be able to locate cerebral diseases with the accuracy with which the old phrenologists could place the mental faculties; their abdominal surgery may lack the boldness of "Jack the Ripper;" they may not distinguish the bacterium termo from the comma-bacillus, but they will in a few years be able to apply the resources of medical science and treat the peculiar diseases of their localities with a practical shrewdness which would astonish those of more ambitious training.

The published questions and answers of the State Board of Examiners of Virginia are occasionally to be found in the medical press of the country, and present some of the strongest arguments that can be advanced in favor of restrictive medical legislation. The profession, and especially the public, are to be congratulated on the fact that in that State at least it will not be possible for those who made the following responses to legitimate questions to practice medicine:

Symptoms of oedema of the glottis are that the patient feels husky and has sore throat. I would amputate it if necessary. I would do the operation within three or four months if it was a bad case.

The dose of morphia sulph. for a child of five years, hypodermically, would be one-fourth grain, and if that doesn't give relief, I would give one-half grain.

The dose of antipyrin for a child five years old is fifteen grains every three hours.

The kidney is a muscular formation, in shape oblong, color quite dark, weight about one pound to one and a half, but may vary considerably.

The sympathetic system is composed of all the filament of nerves that start from the spinal cord, and are distributed to all parts of the system, especially the brain. The cervical portion ramifies the encephalon in general. The dorsal portion ramifies the anus.

Extra uterine pregnancy may be a fungoid growth or tumor fibroid in its character or any extra growth in the uterous would be called extra uterine pregnancy.

A breech presentation may be known by the sense of touch, the buttox being different in formation from the cranium. The anus is different from the mouth, absence of tongue and nose. Get your finger in the inguinal region soon as possible and assist your patient by firm but gentle tension.

Dr. John B. Roberts, one of the Fellows of the Academy, in a paper read before the Medical

* The chief work of reference for all inquirers as to the provisions of laws regulating medical practice is, of course, the Report by Dr. Rauch of the Illinois State Board of Health, especially its latest issue.

Jurisprudence Society of Philadelphia, last winter, referred to the same subject, and related a number of similar illustrations of ignorance, some of which were quoted from an interesting paper presented some time since to the American Medical Association by Medical Director Albert L. Gihon, U. S. Navy, a former President of our Academy:

The normal temperature of the human body is from 112° to 140°.

The temperature of the system is variable. In health the cuticle stands at 70°.

The average respirations are 70 per minute.

The best way to facilitate the expulsion of the placenta is to let the woman get up and walk about the room, allowing five minutes to elapse after delivery before requiring her to get up and walk.

Phymosis is the result of old age.

The difference between galvanism and electricity is that one of them is the substance itself and the other its use.

Phosphorus burns and makes nitrogen gas.

The technical name of rhubarb is columbo.

The Minnesota Board has also published some of the far from brilliant replies of applicants in that State (*North-Western Lancet*, May 1, 1890). The public should feel happier in the exclusion from the opportunity to practice of such a respondent as he who stated, in reply to a question, that "the gland penis passes through the prostate gland;" or that "in cases of death from suffocation the bronchia remain *in situ quo*;" or that "one of the principal symptoms of scarlet fever is malice on the part of the child . . . the sequelæ may be death or recovery."

Perhaps if education should ever approach in its completeness that said to be now required by the University of Coimbra, there would be hope that even these aspirants for a place in the ranks of qualified medical practitioners might in time be enabled to pass a respectable State's examination; for we learn that in that institution fourteen years' study are exacted; six spent in obtaining an ordinary education, three in a preliminary scientific course, and five in purely medical studies.

We will now, as briefly as possible, pass the various States in review, quoting the opinions of recognized authorities, as exhibited in their personal correspondence up to the latest possible date.

Dr. Jerome Cochran, Senior Censor, Medical Association State of Alabama, writes as follows:

No change has yet been made in our law to regulate the practice of medicine, but efforts to have the law amended are now pending before the General Assembly, with the prospect in our favor.

We understand that additional legislation is required in that State to enforce the penalty.

Dr. R. G. Jennings, Secretary of the Arkansas Industrial University, at Little Rock, writes as follows:

In 1881 was passed an Act "To Regulate the Practice of Medicine and Surgery in the State." This Act has not

been amended or changed, although we have at every session of the legislature made earnest efforts to do so. It establishes County Boards of Examiners, and an applicant passing *any county* board, however careless and indifferent it may be to the interests and welfare of the people, is granted the license or privilege of exercising, or rather practicing, in any other county in the State. Some county examiners, therefore, who are *liberal for the fees*, do most all the examining, and thereby injure the profession. We hope to accomplish something in the way of a change this winter, the legislature convening in January, 1891.

In regard to California, a recent editorial in the *Pacific Medical Journal* (August, 1890) makes the following pointed remarks:

California needs a new medical law because her standard is too low, and there is no other way by which to elevate it. It is much lower than that required by many other States in the Union, by Canada and by most, if not all, European countries. The result is plainly apparent. California will become the dumping ground for third-rate practitioners who cannot receive recognition in other places. The *pro rata* of physicians to the population, already high, will assume frightful proportions, and this, coupled with the fact that many of these have been forced from other places because they were illy qualified, or unscrupulous, or both, puts the medical future of California in no flattering position. The people will be in a great measure at the mercy of ignorant and bad men, and the medical profession will suffer disgrace and defeat. This is not an admission that scientific medicine is not able to take care of itself. It means that we, as a State, cannot afford to be behind all others and be compelled to receive and use the material which they cast out as refuse. France has one physician to every 3,000 people, Germany one to 1,500, the United States one to 600, and California, that boasts of her climate and the good health of her people, one to 500. A year ago, Los Angeles had one physician to 301 people, and San Jose one to 221.

From Dr. Frank H. Caldwell, Secretary of the Orange Co. Board of Health, Fla., we learn that:

There has been no change in the laws regulating the practice in Florida. The law in the Seventh Judicial District has been effective; we have succeeded in convicting several who were endeavoring to practice without the necessary license. Our Board will meet on December 12 and there are quite a number of applicants for certificates. Our standard is 80 per cent. As soon as I can get out the questions for examination, I will forward you a copy; and I feel assured that you will recognize the fact that none but qualified practitioners will be able to pass the examination which we give.

The report of the State Board of Health of Illinois for 1889 illustrates the efficacy of its laws for the regulation of medical practice. When the law went into effect there were in the State, engaged in practice, 7,400 persons. Of these 3,600 were graduates from some medical college, while 3,800 were non-graduates. In other words, the graduates constituted only 48 per cent. of all engaged in practice. On January 1, 1890, the percentage of non-graduates to the whole number was only 9. From 3,800 the number has been reduced to 575. The total number of physicians in the State is less now than it was twelve years ago.

Dr. J. F. Kennedy, Secretary of the Iowa State Board of Medical Examiners, writes:

The only change in the Medical Practice Act of this

State since its passage was an amendment to issue certificates to those who had passed satisfactory examinations before other State Boards. The law originally did not admit this. Our law is working well. Its beneficent provisions are thwarted somewhat by our pharmacy law, which allows the Commissioners of Pharmacy to issue a vendor's permit to itinerating medicine proprietors, whether physicians or not. Under this permit they practice the grossest charlatanism. Our medical law is yearly growing in favor. It is too liberal in that it allows all kinds of advertising and takes no cognizance of professional or moral character, except that it permits the revocation of a certificate upon the conviction of a felony in connection with his practice.

Dr. J. N. McCormack, Secretary State Board of Health of Kentucky, states that the law has met with general favor with both the medical profession and people. He calls especial attention to the provision which prohibits traveling empirics from registering or practicing at any place in the State. His best information is that it has forced about 400 to either retire from practice or leave the State.

Dr. Lucien F. Salomon, Secretary of the Louisiana State Board of Health, writes that no changes have recently been made in the laws regulating the practice of medicine, and adds:

In regard to my views as to the working of the present Act regulating practice in this State, I have nothing to add to what I have already expressed in a previous communication, except that time has to a great extent cured the defect which existed under section 3 of Act 1882 of the General Assembly of Louisiana, the law under which we are now working. It is very seldom that we now have an application from any one to be registered without a diploma and having been engaged in the practice of medicine for a period of five years prior to the passage of the Act, as provided in said section.

At the last session of the Legislature efforts were made to have the present law amended, but without result. A bill was introduced providing for the appointment of an Examining Board and other regulations, but was killed in committee, owing to the efforts of the homeopaths, who had friends in the Legislature.

From Dr. A. G. Young, Secretary of the Maine State Board of Health, we learn that there have been no changes as to laws regulating the practice of medicine, and that there are no laws whatever bearing upon this point. Some of the legislators who will meet in January are said to be interested in doing something in this direction.

Dr. George H. Rohé, of Baltimore, Md., writes that the last Legislature of Maryland passed a new medical law, but the Governor failed to sign it. They are therefore living under the old law passed in 1888, which is not enforced.

Dr. H. B. Baker, Secretary of the State Board of Health of Michigan, writes as follows:

I think the profession in Michigan are much nearer an agreement on what should be done, than ever before.

At the October, 1890, meeting of the State Board of Health, the subject of an attempt to stop the continued influx of unqualified practitioners was brought up through a communication from George Duffield, M.D., Secretary of a committee of the State Medical Society, whereupon the following preamble and resolutions were adopted:

WHEREAS, It is agreed by all classes of people that the public health would be much better protected if none but properly qualified persons were permitted to practice

medicine, and thus to have in their keeping measures relative to the same.

Resolved, That it is helpful to the public health through judicious legislation to so regulate the present legal medical practitioners in Michigan as that through representatives elected by themselves they shall guard the entrance to the profession by a preliminary examination of students and a final examination of graduates of colleges and of persons who are practitioners who come from other States, so that the entire medical profession of this State shall be united in the effort to improve the qualifications of its new members.

Resolved, That the Secretary of this Board be directed to transmit a copy of the foregoing preamble and resolution to the chairman of the committees on public health in the Senate and House of Representatives in the State Legislature, as soon as it is in session.

Dr. Arthur Sweeney, Secretary of the State Board of Medical Examiners of Minnesota, writes as follows:

No changes have taken place in the Minnesota Medical Act since its passage in 1887. The three years of legislation in Minnesota have demonstrated the wisdom of the framers of our law. During the two years from July 1, 1888, to July 1, 1889, 220 licenses were granted by the former Board, under the law which recognized diplomas from reputable schools and exacted examinations only from non-graduates. During the three years of the present law 223 applicants have been examined, of whom 138 were licensed, 61.42 per cent., and 85 were refused, 38.58 per cent. This lessened number of applicants is due in part to a wholesome fear of not being able to pass the examination on the part of poorly educated physicians, and in part to that provision of the law which requires that candidates having graduated later than 1887 must present evidence of having attended three courses of lectures of at least six months each, thereby excluding graduates from short term medical schools.

The law has passed the stage of opposition, its beneficial operation awakening a public sentiment in its favor which ensures its permanency. The law is administered, not in the interest of the physician, but for the benefit of the community, in order that the public may be assured of the character, ability and education of its physicians. It has proven a bulwark against quackery and the less obvious peril of ignorance and incompetency, and has practically rendered Minnesota free from "cancer doctors," itinerant medicine vendors and other mountebanks that disgrace so many States. It has operated with severity upon half educated and incompetent physicians, and has mercilessly driven from the State all except those whose ability and fitness were demonstrated by rigid examination. The law has reduced the number of "irregulars" those who were non-graduates or who were licensed by reason of practice prior to the passage of the law, from 351 in 1883 to 293 in 1888, and to 149 in 1890. This is due to the fact that the advent of a better educated and more scientific class of physicians has driven to the wall the larger part of that dangerous element.

The especial benefit of the law is in the fact that the standing of the physician in the eyes of the public is improved, for practically the license of the Board is a certificate of ability and competency.

My experience leads me to believe that the best results in the line of higher medical education can be derived from compulsory preliminary examination by medical colleges, the lengthening of the term of instruction, and the separation of the diploma-granting body from that which gives the instruction. The establishment of a uniform medical law in all States, on the basis of that recommended by the American Medical Association, would be a great benefit, but, unfortunately, the time has not yet come to render it feasible.

In conclusion I would say that the Minnesota medical

law has proven its efficiency, has raised the standard of medical education within the borders of the State, has driven out and prevented the influx of quacks, has promoted harmony among physicians, and has protected the public. I would call your attention to the fact that North Dakota has adopted a law identical with ours, and that Washington has one based upon it.

Dr. George S. Homan, Secretary of the State Board of Health of Missouri, reports that no changes have been made in the law regulating the practice of medicine in that State since its enactment in 1883. In his opinion the change desirable to be made would be in the direction of placing this duty exclusively in the hands of the medical profession of the State through a body chosen by themselves—briefly the right of self-government.

The *Boston Medical and Surgical Journal*, October 9, 1890, states that the new law of the State of New Jersey, which went into operation recently, contains some features worthy of note.

The execution of the law is vested in a Board of nine members, appointed by the Governor for terms of three years. It is provided that the Board "shall consist of five old school, three homeopaths, and one eclectic," and further, that "no member of any college or university having a medical department shall be appointed to serve as a member of said Board." The new regulations apply only to those who commence practice in the State after the passage of the Act, preceding practitioners being already registered under a previous law.

All examinations are to be in writing and both "scientific and practical, but of sufficient severity to test the candidate's fitness to practice medicine and surgery. If the applicant intends to practice homeopathy or eclecticism, the member or members of the Board of those schools shall examine said applicant in materia medica and therapeutics." A license shall not issue unless the applicant passes an examination satisfactory to all the members of the Board.

A somewhat peculiar feature of the law provides that any applicant refused a license by the Board "for failure on examination, may appeal from the decision of said Board to the appointing power thereof, who may thereupon appoint a medical committee of review consisting of three members, one from each school of medicine, who shall examine the examination papers of the said applicant, and from them determine whether a license should issue, and their decision shall be final. If said commission by an unanimous vote reverse the determination of the Board, the Board shall thereupon issue a license to the applicant. The expense of said appeal shall be borne by the applicant."

The Board may by a unanimous vote refuse to grant a license for the following causes: "Chronic and persistent inebriety, the practice of criminal abortion, conviction of crime involving moral turpitude, or for publicly advertising special ability to treat or cure diseases which, in the opinion of said Board, it is impossible to cure."

The power of the Board is evidently very great, but it would be difficult to arrange a greater number of safeguards. In fact, it may be a question whether the safeguards against possible injustice are not so great as to hamper the action of the Board.

In New York State, it was mentioned, editorially, in THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, that:

The law approved by the Governor on June 4, 1890, will mark a new era not only in New York, but, incidentally, in the entire country. . . . The first cardinal point which occurs to us is this: that the State presumes to re-

affirm and to emphasize the fact that it alone has jurisdiction over the practice of medicine within its own limits. It may not only determine as to who may practice medicine, but it also presumes to assert what the qualifications of its practitioners shall be. In the exercise of this power it recognizes the responsibilities which it assumes, and seeks to make the best provision. In the second place, it proposes to redeem the profession from illiteracy by the requirement of a satisfactory preliminary education as a condition to an entrance upon the study of medicine. In the third place, it provides for a definite and uniform standard of examinations, and each and every student must attain to that standard as a condition to graduation. In the fourth place, it divorces medical teaching from the licensing power. To this end the Examining Boards are under the supervision of special examiners, who are appointed by the Regents, and who themselves cannot be members of those Boards. And finally, it compels the colleges to teach their students three years, instead of two.

We have, then, in this single bill, the requirements of preliminary education; a definite standard for examinations; a separation of teaching from the licensing power; and a three years' college course. Thus grandly has the State redeemed itself from what had threatened her as a sad misfortune.

The *Medical Record*, in an editorial written soon after the approval of the bill, is not wholly satisfied with its provisions. It states that:

The law allows any person who wishes to matriculate as a medical student, to pass his preliminary examination at any time during his first three years of study. This practically nullifies the law, and permits any man to enter upon the study of medicine without a test of his educational fitness. The law, as it stood before, had some defects which could have been easily remedied. The present amendment totally destroys its force. It was secured, as is well known, through the political influence of the managers of certain medical colleges of this city, and against the wishes and judgment of the medical profession of the State as a whole. The second piece of pernicious legislation was the enactment of a law establishing three Boards of Medical Examiners. This was done, also, despite the protests of the vast majority of the medical profession, including even many prominent homeopaths. We trust that next winter there will be concerted action to secure the repeal of the triple board law. A law was passed providing that physicians who come from another State must pass a qualifying examination before beginning to practice here. This law is a wise and proper one.

Dr. W. J. H. Bellamy, of Wilmington, N. C., writes as follows:

No one can now practice medicine in North Carolina unless licensed by our Board of Medical Examiners. The penalty for violation of law is fine and imprisonment. All physicians had to register prior to January 1, 1890. Since that time only licentiates can register. The law seems to be working well.

According to the new law regulating medical practice in North Dakota, no one can practice medicine until he has passed an examination in all the primary and final branches. No one will be admitted to such examination until he has taken at least three courses of lectures of six months each.

Oregon has a Medical Practice Act, and it was not long in force before it drove from one of the cities a certain advertising specialist. A local paper commented upon this result as follows:

Upon what hypothesis the Board rejected his diplomas

we can't divine. Dr. A—— is one of the oldest specialists on the American Continent, and seventeen years ago he practiced in this city for a period of four years. He has practiced in San Francisco, Philadelphia, Chicago, and many other cities of like importance, and is recognized as one of the greatest eye and ear physicians of this age. This unfortunate circumstance will certainly be an unwelcome piece of news to the press of this coast, as the doctor is one of the heaviest, and most extensive advertising physicians in America, and had he located in Portland, as he expected to do, he would have advertised in every newspaper on the coast, and probably spent \$50,000 the first year with newspapers.

The *Medical Record* recently referred as follows to legislation in Oregon:

In a bill to regulate the practice of medicine, recently introduced in the Oregon Legislature, there is a clause, providing for the revocation of licenses for "unprofessional conduct," which is defined in the bill as follows: First, the procuring, or aiding or abetting in procuring, a criminal abortion. Second, the employing of what are known as "cappers" or "steerers." Third, the obtaining of any fee on the assurance that a manifestly incurable disease can be permanently cured. Fourth, the wilfully betraying of a professional secret. Fifth, all advertising of medical business in which untruthful and improbable statements are made. Sixth, all advertising of any medicines or of any means whereby the monthly periods of women can be regulated or the menses reestablished if suppressed. Seventh, conviction of any offence involving moral turpitude. Eighth, habitual intemperance.

At the last annual meeting of the Pennsylvania State Medical Society, it was decided that the presidents of the State and county medical societies should constitute a legislative committee "to secure the passage of a medical law that will give protection to the people of this State against incompetent practitioners of medicine." The present registration law has never been regarded as anything more than a stepping-stone to restrictive laws of greater force and character.

Dr. H. D. Fraser, Secretary of the State Board of Health of South Carolina, reports that the laws regulating the practice of medicine have undergone no recent changes. The profession is satisfied with them, as they seem to be all that is necessary.

Dr. D. E. Nelson, Secretary of the State Medical Society of Tennessee, states that

The only laws that have ever been passed by the legislature of this State were passed two years ago, and although imperfect as you will see, or have seen, they work a great deal of good, and I think, after some modifications, which we hope to secure at this winter session of the legislature, will do a great deal more of good. There is no rebelling against the law. There are two points in our law which I think should be changed. One is that any one can act as a *midwife*; the other is that all parties should be subjected to an examination, for, as we all do well know, some unworthy men are allowed to practice with a diploma from what stands as a good school.

Dr. George Cupples, the efficient Chairman of the Committee on Legislation of the Texas State Medical Association, has prepared a circular letter to the medical profession of that State in reference to the total neglect of preventive medicine in Texas, through the failure of previous legislatures to frame enactments on sanitation, notwith-

standing the earnest and repeated prayers of the profession; the widespread necessity for such legislation, has placed that great and wealthy State in a contrast anything but honorable, with the position occupied in this matter by no less than thirty-five States which have created Boards of Health, charged with the care of the public health, and with the care of admitting none but competent physicians to practice medicine and surgery in their limits. A draft of a law is offered by this committee which, it is hoped, will be adopted by the legislature when it convenes.

The Medical Examining Board of the State of Washington consists of nine members, appointed by the Governor, three only of whom are regular physicians. A committee of the State Medical Association was appointed to draft a communication to the Governor protesting that over 700 of the 800 practicing physicians in the State are regular, yet the profession is in a minority on the board, and asking that a redistribution may be made whereby they may have a pro rata representation in that body.

A correspondent of the *Medical News*, under date of August 16, 1890, referring to the examination in that State, writes that

Laying aside all prejudices, a perusal of some of the questions of the "physio-medic" and eclectic members will show the injustice of having men of that class on the board. During the examination the writer carefully copied the questions, and in some instances, the spelling—for the question sheets came to us in the handwriting of the members by whom they had been prepared. The "physio-medic" asked, "What is *portusae*?" and also the very comprehensive question, "What does delayed dentition prognosticate?" To this last I could not answer, nor could the two or three members of the board, to whom I afterward repeated the question. In Diseases of Women he questioned upon "*leucorrhoea*," "*catarrh of the uterus*," and "*dysmenorrhoea*." Other questions of his were, "Define *mammary abscess*," and "What is *pelvic abscess*?" while the last question was upon "*lacerated perineum*."

The eclectic prepared questions on anatomy and physiology, one of which read as follows: "Name the divisions of the abdominal aorta, large branches, and from where does the lower extremities derive their blood supply?" Another asked, "What's the *fermentary* condition of pepsin in the stomach?" to which we afterward discovered he wished us to answer "Hydrochloric acid." Another question was, "What's the effect of too much red corpuscles in the blood?"

Under the heading of Preventive Medicine in the list of questions prepared by a homeopath, we found two as follows: "What means would you take to resuscitate from an overdose of chloroform?" and "How would you treat a case of poisoning from opium or morphia?" He evidently looks at the subject broadly, and thinks that any means of preventing death should be placed under the head of preventive medicine.

Dr. T. A. Harris, Parkersburg, W. Va., says:

I think that with time the laws regulating the practice of medicine in this State are being enforced. At first there was some difficulty, but I think with each year that difficulty has grown less, and year by year there is less objection manifested and less disposition to evade them; and further, the body of the people, the laity, are more and more disposed to support them. At first there was a feeling that certain doctors had gotten the law

passed for their personal advantage, but the people are coming to see the true purpose of the law; and it is certain that neither this nor any law can be enforced in face of a decided popular opposition.

Dr. J. T. Reeve, Secretary of the Wisconsin State Board of Health, writes that there have been no new laws enacted and no recent changes have been made in the laws of that State.

Dr. Francis W. Campbell, Secretary of the College of Physicians and Surgeons, Province of Quebec, states that the present Medical Act has been in force in this Province for ten years, and seems to give, upon the whole, good satisfaction.

Dr. R. A. Pyne, Registrar of the College of Physicians and Surgeons, of Ontario, Dominion of Canada, writes as follows:

There have not been any changes made in our Medical Act since the year 1887, when we got some amendments, the important features of which are, limiting the time of action in cases of malpractice. The other part of the amendment refers principally to the erasing of names for unprofessional conduct; some similar powers exist in the Imperial Medical Act, and every year they strike the names of practitioners from the list for irregular unprofessional conduct.

This paper concludes the series of annual reports in regard to "Laws Regulating Medical Practice," which it has been my pleasant duty to prepare and offer, as Secretary of the Academy, annually for your consideration, and which, by my resignation of the office, it will become the duty of my successor to continue. A retrospective glance at these annual sketches, from their inception, would exhibit evidence of gratifying progress in the different States of this country in the effort to repress quackery and to protect the public against the imposition of the ignorant and incompetent.

THE BASIS OF SCIENTIFIC MEDICINE AND THE PROPER METHODS OF INVESTIGATION.

*Introductory Lecture delivered in the Post-Graduate Medical School
of Chicago, January 6, 1901.*

BY N. S. DAVIS, M.D., LL.D.,
OF CHICAGO, ILL.

Gentlemen and Members of the Medical Profession:

We have assembled this evening to inaugurate the first formal course of post-graduate medical instruction in this building, recently completed and dedicated to the interests of the sick and to an important department of medical education—a department, indeed, that had its first beginnings in this city and in connection with the Chicago Medical College.

At the close of the regular annual college term of the Chicago Medical College in the spring of

1880, the faculty inaugurated a well arranged course of four or six weeks' duration, exclusively for the benefit of practitioners or graduates in medicine. The course was largely clinical and practically demonstrative, but included also a review of whatever was new in etiology, pathology and therapeutics. It was attended by thirty-nine practitioners from this and seven of the surrounding States, and was repeated annually for several years. Its marked success attracted general attention, and speedily led to the institution of similar courses in connection with the Rush Medical College, and with several of the leading medical colleges in other cities. This rapid increase in the number of such courses in different cities, and nearly at the same season of the year, so divided the number of practitioners who could afford to leave their practice, that the number in any one college was too limited to make it profitable to maintain them, which naturally led those teachers connected with the several schools and hospitals to unite in forming separate schools for post-graduate instruction, in which short courses to limited classes could be given, in nearly all parts of the year, and on all practical subjects of importance. The important department of post-graduate medical education, thus inaugurated in this city only ten or eleven years since, has not only demonstrated its importance and established its permanent institutions, called polyclinics and post graduate schools, in the leading cities of this country, but the same is now beginning its development in London and other places in Europe. It is appropriate, therefore, that I should embrace this opportunity to emphasize both its origin and gratifying progress, before entering upon the discussion of the topic announced for this evening.

What constitutes the basis of scientific medicine, and what methods of investigation are best adapted for its study and more complete development, are questions worthy of most thoughtful consideration. There are still those, both in and out of the profession, who deny that medicine has any scientific character, and who talk and write of old and new "schools of medicine" consisting of the theoretical dogmas of some dreamers of past generations. But in doing so they only betray the shallowness of their own attainments, and especially their ignorance of the real medicine of to-day.

If there be no scientific basis for modern medicine, then there are no sciences known to the human family except those of pure mathematics; for the facts and materials that constitute the different branches of medicine are taken or segregated from every other science or department of human knowledge. Some sciences, as the mathematical, are composed of such facts and propositions as are capable of being so placed in relation to each other as to admit of the deduction of fixed and uniform conclusions, and hence are called

Dr. Houghlson was, by a special complimentary resolution of the Academy, at its annual meeting December 4, 1900, appointed a committee of one to continue annually his interesting reports on the progress of medical legislation and the working of laws regulating medical practice. Editor JOURNAL A. M. A.

"deductive sciences." Others are composed of so great a variety of facts or elements, many of which are influenced by varying or unstable causes, that they admit only of careful comparison and classification in such manner as to admit of conditional inductions or inferences instead of uniform conclusions. Hence, since the days of Bacon, they have been called "inductive sciences." To this division belong geology, botany, and, indeed, all the branches of knowledge concerning the vegetable and animal kingdoms of nature. No one of these branches of knowledge or natural sciences are complete. That is, all the facts and relations belonging to any one of them have not been fully observed and classified; yet no one denies the propriety of calling them sciences, incomplete, it is true, but each progressing towards completion with every additional accurately observed fact or improved means and method of investigation. Every recognized branch or department of modern medicine is composed of facts and principles belonging to the wide domain of natural and physical sciences and their application to the relief of human suffering, and consequently is fully entitled to the name of "inductive science." Until full and accurate dissections had revealed all the structures of the human body and their relations to each other, and observation and experiment had revealed the uses or functions of each part, there could be no science of human anatomy or physiology. And until the progress of elementary and organic chemistry had revealed the composition of the fluids and solids of the human body in health and disease, there could be no science of medical chemistry and materia medica. All these have had their origin and development during the last three centuries. And yet human anatomy and physiology including histology, and medical chemistry and materia medica, constitute the basis of all scientific medicine. All that is valuable or established in etiology and sanitation has resulted from the application of medical chemistry and histology to the study of the causes of disease; pathology and pathological anatomy are but abnormal physiological and anatomical conditions; therapeutics consists in the adjustment of the materials of materia medica to the control of pathological processes; and the details of operative surgery and midwifery are but the application of anatomical and physiological knowledge to the correction of deformities, the relief of injuries and the removal of obstructions to which the human body may be liable.

Hence, I repeat that those departments of the great fields of natural and physical sciences known as anatomy, histology, physiology, pathology, medical chemistry and materia medica, constitute the acknowledged basis of modern medicine; while therapeutics or practical medicine, surgery, and sanitation or preventive medicine, are strictly ap-

plied sciences developed by the same methods of observation, experiment and induction that have brought into existence all the other inductive sciences. Dr. W. N. Broadbent, in his interesting address before the British Medical Association at its recent meeting in Birmingham, on "Therapeutics as an Applied Science," says "that therapeutics must always belong to the order of applied sciences, and will bear much the same relation to physiology in an extended sense as engineering to mathematics. Just as engineering is applied mathematics, therapeutics will be applied physiology." If in the foregoing paragraph, and throughout his address, Dr. Broadbent had substituted the word *pathology* for physiology, his declarations would appear to me far more correct. Physiology is the science that embraces all the facts, principles and laws relating to the healthy or normal processes or changes taking place in living beings; and may be properly styled the science of health. Pathology is the science that embraces all the known facts, principles and laws relating to such deviations from the normal or physiological processes as constitute disease, and is, therefore, physiology applied to the study of abnormal conditions. Therapeutics relates to the application of remedies for the control, not of healthy or physiological processes, but of morbid or pathological conditions, and is consequently applied pathology.

Dr. Broadbent fairly concedes this when in another part of his address he says: "By therapeutics we mean all those measures by which we combat and endeavor to subdue disease, and if we ask what would fulfil the conditions of therapeutics as a science, the answer would be, a complete knowledge of the processes of disease on the one hand, and of the mode of action of remedies on the other."

This is a concise and correct statement of the real relations of therapeutics to pathology, and clearly points to those methods of investigation by which the scientific character of both can be rendered more nearly complete. As the "processes of disease" pathology are simply deviations, in some direction, from the normal standard of the processes of health (physiology), a successful study of the former must have for its basis or point of departure a complete knowledge of the latter. In other words, our knowledge of the physiological or natural processes taking place in every organ and structure of the human body, and the agencies by which they are maintained, must be complete, before we can appreciate with clearness and certainty the pathological or abnormal processes taking place in the same structures, and the causes that may produce them.

The present advanced condition of organic and analytical chemistry, with the varied instruments of precision founded on mathematical and physical laws, furnish the means, if correctly and patiently

directed in the proper lines of experimental research, for making our knowledge of human physiology as complete as an inductive science can be made. And the same means, applied with the same accuracy and patience to the investigation of the morbid processes constituting disease, would speedily render our knowledge of pathology sufficiently complete to constitute a reliable basis for an applied science of therapeutics.

I will go one step farther, and venture the assertion that if the same modern chemical, philosophical and mathematical resources for observation and experimental research, were carefully and accurately directed to the study of etiology, or the causes of disease, that important department of the great field of medicine, hitherto filled with a chaotic aggregation of partially observed facts, fanciful speculations and false assumptions, would soon attain all the characteristics of a true science, and furnish a more reliable basis for sanitation, preventive medicine, and one of the most important indications or purposes in the treatment of disease.

One of the most important obstacles to real progress in scientific development and accuracy, is the want of perseverance on carefully devised plans for insuring completeness of investigation before announcing results.

Almost every problem within the domain of etiology, pathology and therapeutics, is complex from the number of the elements requiring consideration for its correct solution, and sometimes the coincident work of different individuals to secure the same end. Very much of our scientific and experimental work is done in fragments, and necessarily results in the development of isolated facts and partial views, filling the pages of our literature with ever changing and often contradictory inductions. For example, during the last two decades of time it has been claimed that abnormal temperature or pyrexia is the chief pathological factor in the general fevers; and by logical inference that antipyretics constitute the chief remedies. Hence, as often as the pharmaceutical laboratories developed a new, complex, artificial compound of the coal-tar series, and the experimental therapist proved it capable of reducing the temperature of the body, it was applied with the greatest freedom for the control of the pyrexia of all general fevers. The two isolated facts of high temperature and the antipyretic property of the remedy, were the sole guides of the physician, and in many instances to the ultimate detriment of his patients. That complete knowledge of the processes of disease mentioned by Dr. Broadbent, requires not only the fact of high temperature or pyrexia, but also the processes by which it is produced in each variety of fever. Physiology has taught us that in the living, healthy animal body there are in constant operation processes by which heat is produced, and other processes by which it

is dissipated, and that the natural temperature is the balance or average result. Consequently, abnormally high temperature must result either from a diminution of the processes of heat dissipation, or from an increase of those of heat production, or from an unequal alteration of both. It follows that one remedial agent, when properly used, will act as an antipyretic by increasing heat dissipation, and another by diminishing the heat production; and the true scientific basis for choice of remedies in a given case of pyrexia, is a clear knowledge of the *modus operandi* of the remedial agents, and an equally clear appreciation of the processes on which the abnormal temperature depends.

Another serious obstacle to scientific progress consists in the frequent formulation of inductions, or more properly assumptions for practical guidance, founded on an inadequate number of facts, and sometimes on mere analogies. Thus, when in the progress of organic and physiological chemistry, it had been fully demonstrated that the chief proximate elements of our food could be divided into two classes, one of which was composed essentially of oxygen, carbon and hydrogen, and the other of these three with the addition of nitrogen, the first were called hydro carbonaceous and the latter nitrogenous foods. And as the organized elements of animal tissues were composed of the same four elements, it was *assumed* that the nitrogenous elements of food were appropriated to the growth and repair of such tissues; and as oxygen disappeared through the air-cells of the lungs and was replaced largely by carbonic acid, as in combustion out of the body, it was *assumed* with equal positiveness that the hydro-carbonaceous food elements united with oxygen in the living body, resulting in the formation of carbonic acid and water and the evolution of heat, and hence were called respiratory foods.

The only facts clearly demonstrated by experimental investigation were that the oils, starch, sugar and gum in our food were hydro-carbons, and that the albumen, fibrin, casein, gluten, etc., were nitrogenous, on the one side; and on the other, that the living animal structures were nitrogenous, with a constant consumption of oxygen and liberation of carbonic acid and heat. The inductions from these facts, that the carbonaceous food elements only were converted into carbonic acid, water and heat; and that the nitrogenous were converted into tissues, were simple theoretical assumptions, without the support of a single well devised series of experiments for their demonstration, while many accurately observed facts militate against their correctness. These theoretical assumptions were not limited to the food elements I have named, all of which are the products of vegetable or animal growth, but were extended to many other substances of entirely different origin merely on account of analogous chem-

ical composition. For example, the chemist readily demonstrated that all the varieties of alcohol were composed of oxygen, hydrogen and carbon, and consequently were chemically pure hydro-carbons; and as the ethylic or common alcohol was being largely used in fermented, and distilled drinks, it was directly assumed that it united with oxygen in the living system, resulting in the production of carbonic acid, water and heat; and was placed in the front rank of respiratory foods. These simple theoretical assumptions, plausibly illustrated by many supposititious chemical formulæ, have occupied a prominent position on the pages of both medical and general literature from the days of Baron Liebig to the present time. And yet, all the carefully devised and patiently executed experiments of the chemico-physiologists of Europe and America have only proved that the hydro-carbons derived from vegetable and animal growth undergo molecular or metabolic changes in passing through the digestive organs before appearing as natural elements of the blood, while those derived from fermentation or retrograde processes undergo no such molecular changes in the digestive organs, but are rapidly imbibed and appear unchanged in the blood, thereby demonstrating that mere analogy of chemical composition can afford no safe basis for the inference that the same analogy will apply to their behavior when taken into the living body. I may add that these numerous experimental researches, aided by all the modern instruments of precision, have failed to develop any evidence that the presence of the alcoholic class of hydro-carbons in the living system is productive of either carbonic acid, water, heat or any other kind of force, but the reverse. Indeed, the plain tendency of present experimental researches is towards demonstrating the fact that the vegetable kingdom only can assimilate and grow from inorganic matter and the products of retrograde or destructive processes, while the animal kingdom assimilates and appropriates to itself only the products of vegetable and animal growth.

Still another potent hindrance to scientific progress, is the constant tendency to concentrate all attention on the results of any new line of investigation that may be started to the neglect or rejection of facts and inductions previously well established, and their value verified by abundant clinical observation. Up to the close of the first quarter of the present century the processes of disease were studied and classified by a patient and close observation of the actual symptoms or phenomena of disease at the bedside of the patient; and the effects of remedies were determined by careful study of the results of their empirical use with only the limited aid offered by general chemistry. The same methods of observation were applied to the study of the causes of disease, especially in relation to the conditions of the climate, soil, water,

seasons of year, age, sex and occupation. It was preeminently the era of symptomatology and active medication, during which were established many important facts in both pathology and therapeutics, and was accompanied by fair success in the treatment of disease as reliable records will show. But with the second quarter of the century came the brilliant studies in morbid anatomy led by Louis, Chomel, Gerhard and others, resulting in more accurate differentiation of diseases and more exact knowledge of the structural changes in the several stages of their progress.

To this was soon added the application of the microscope to the study of minute anatomy, both normal and abnormal; and hence the study of morbid processes at the bedside rapidly gave place to the study of the results of morbid processes in the morgue and in the laboratory, culminating in the evolution of the cellular pathology of Virchow and the substitution of pathological anatomy for pathology proper. Just in proportion as these structural changes and the associated cell proliferations came to occupy the attention of the profession, carrying with them the thought that diseases were fixed processes of development, maturity and decline; in the same ratio active interference with remedies was discouraged and an era of therapeutic skepticism, expectancy, or faith in the *vis medicatrix nature* as presented in the popular writings of Bigelow, Forbes and Holmes, ensued. All the active therapeutic measures of the preceding era were declared unnecessary or injurious and were superseded by fresh air, more cleanliness, more food, and patience until the climax was reached in the declaration of Chambers, that all disease is a diminution of life, and all proper treatment is to sustain or support the life. Consequently food and so called stimulants became as popular as depletion and evacuants had been during the preceding era. But only a few decades were allowed to pass before the continued use of the microscope in the study of pathological anatomy, revealed the fact that in all the protracted fevers, or acute general diseases, extensive molecular and tissue degenerations were developed with an increasing ratio of mortality. This led to the erroneous opinion that the protracted high temperature of pyrexia was the cause of such general molecular degeneration, and as a necessary inference, that the most important purpose to be gained by treatment was to hold the temperature in check by antipyretic measures. The cold douche, the cold bath, the cold sponging; sedative or large doses of quinine, salicin, and other antipyretic remedies were so rapidly brought into use, that the third quarter of the century had hardly closed before acute diseases were being treated with more active agents and more heroic doses of medicine than during any part of the first quarter. This reaction towards

heroic medication has been greatly increased by the application of the microscope to the study of etiology, and the consequent rapid increase of knowledge concerning the relation of certain microorganisms to the prevalence of diseases.

The discoveries of Pasteur, Koch, Eberth and many others, in this field, have so completely concentrated the attention of the profession on bacteriology and pathogenic microorganisms, and the consequent search for antiseptics and germicides as therapeutic agents, that the bacteriology and bacteriological therapeutics of to-day have as fully superseded the pathological anatomy with its therapeutic skepticism of thirty years since, as did the the latter symptomatology and antiphlogistic therapeutics of the first half of the century. And the century bids fair to close with the profession combating disease not only with as active or heroic measures, but also with many of the same remedies that were most relied upon at its beginning. Then, opiates, to relieve pain, the two chlorides of mercury and iodine to control morbid processes, and quinine and kindred alkaloids to subdue fevers, were the chief remedies in the hands of the general practitioner; and now, under the names of anodynes, antipyretics, antiseptics and germicides these same remedies are being used with even greater freedom than at any former period in medical history. It is not the adoption and vigorous prosecution of these successive methods of investigation during the present century that constitutes an evil, for each was necessary and has added greatly to the stock of most important medical knowledge. But the evils result from the spirit of exclusiveness, dogmatism and indulgence in positive inductions from insufficient facts that characterize their pursuit, and the consequent neglect or disparagement of all that had been done before. It is the indulgence of this spirit, that makes those entering the profession during any given era, regard its methods of investigation and their results, as the chief topics worthy of their attention and strongly encourages the neglect of medical history and begets a narrowness of mental vision highly detrimental to true medical progress. Instead of permitting every new appliance or method of inquiry that opens before us a new or additional field for investigation to displace or supersede all others and engross our whole attention, the true philosophical spirit of inquiry requires us to hold all the facts and inductions that have appeared well established in one era until those of the next have been studied in all their aspects and relations to each other and to all that had preceded. A close adherence to this rule would effectually check the strong tendency to draw hasty conclusions from an inadequate number of facts or observations, and the results of every new line of inquiry would constitute real additions to our knowledge, supplying previous

defects, enabling us to make new or more accurate applications of old remedies or facts, and sometimes furnishing both new and valuable agents and new principles to guide their practical application. All the departments of medicine would thus progress in more harmony, and medical literature would become more free from mere theoretical assumptions and contradictory statements. A more thorough study of the history of medicine, and in consequence, a greater familiarity with the successive steps or stages in the development of its several branches, would enable us to see more clearly the real relations and value of any new fact, induction, or remedial agent that might be proposed. It would also enable us to avoid a common error of regarding facts, propositions and remedies presented under new names, as really new, when they had been well known and used long before, but in connection with other names or theories. Such errors are of frequent occurrence and occupy prominent places in the medical literature of to-day. The true spirit of scientific investigation welcomes every new fact, suggestion, or remedy, but holds it under careful scrutiny until all its relations, chemical, histological, physiological and pathological have been well considered. Is a new remedy proposed for the treatment of an important and well known disease, we need to know its chemical composition and affinities or reactions, its histological development if of organic origin, and its relation to other substances of similar character, to enable us to proceed intelligently and safely with its therapeutic use. Otherwise our use of the remedy must be purely empirical or blindly experimental.

A remarkable instance of this kind is at present occupying the attention of the entire profession and a large part of the public. The eminent bacteriologist, Dr. Koch, has prepared, and presented for use, a remedy that he thinks will cure pulmonary tuberculosis, especially in its earlier stages, and specifies the dose, the mode of administration, and the symptoms or effects produced by it, but positively declines to reveal its chemical composition, its mode of preparation, or even the class of substances to which it belongs. Consequently members of the profession must use it conscious that they are groping in the dark, or they must adhere to the time honored rule against using secret remedies and let it alone until the author and his immediate advisers fully make known the nature and preparation of the remedy and the clinical proof of its efficacy. Taking the remedy, however, simply as proposed by the author, it will require a most careful and connected clinical experimentation through a period of five or ten years, to determine its actual value as a remedy for tuberculosis. A few weeks of its administration is said to remove the more obvious symptoms, as cough, expectorating, etc.; but the

physical signs of tubercular accumulations in the lungs or elsewhere cannot be expected to entirely disappear in less than from six to twelve months, and the question of relapses cannot be reliably determined until from three to five years have passed. Should relapses occur, as seems probable from some indications already reported, the collateral effects of the remedy on the kidneys, the blood, and the nervous system, when resorted to every few weeks or months to arrest such relapses, will be required to be studied with equal care.

The general symptoms produced by the hypodermic use of the remedy, as described by Dr. Koch and his co-laborers, strongly resemble those of an actively poisonous ptomaine or peptotoxine, and hence it is generally supposed to be derived from the cultures of the tubercular bacilli. Only two reasons have been assigned for refusing to publish a complete statement of the composition and mode of preparation of the remedy. These, as given more fully by Von Gossler as the official representative of the Prussian government, are, first, that the actively poisonous nature of the remedy makes it necessary that the utmost care and skill be exercised both in its preparation and use; and second, that Dr. Koch has thus far not been able to render his process of manufacture sufficiently complete to obtain his *fluid* of uniform strength or quality and must consequently test, by actual trial, each product before it can be given out for clinical use. The first of these reasons is the same as that urged by every manufacturer of proprietary and trade mark medicines throughout Christendom, namely, *their* superior skill in manipulating the process of manufacture and the danger that ignorant parties would injure someone by attempting to compete with them if their processes were given freely to the world. The second reason, however, is one of real importance, and should have caused Dr. Koch to adhere to his own alleged inclination not to announce the remedy at all, until his processes for its production were sufficiently complete for reliable results. The present status of chemico-bacteriological investigations show that there are various active or poisonous ptomaines and albumose in bacteriological cultures, morbid products, and in normal secretions, the isolation and preservation of which can generally be accomplished only by complicated and delicate processes. And if Dr. Koch's remedy belongs to this class of substances, it would not be strange if its author should find himself unable to perfect any process by which it can be produced in sufficient quantity and sufficiently uniform quality to be entrusted on the market as a remedial agent.

Investigations have thus far indicated but four methods of treating directly diseases produced by pathogenic germs.

The first is by such remedies as are capable of destroying the germ by direct contact; the sec-

ond, such as if introduced into the living system prior to any active influence of the specific germs, are capable of exhausting its susceptibility to them, and thereby preventing the disease, as in the methods of Jenner and Pasteur; third, by such as when introduced into the system during the progress of the disease so actively attacks and destroys the living plasma or tissue material on which the propagation of the germs depend, that their progress is arrested with a rapid subsidence of the morbid processes and exfoliation or excretion of the necrosed material; and the fourth, by simply accumulation of an excess of the ptomaine or product of the germ itself as illustrated in vinous fermentation when the alcohol accumulates beyond a certain ratio and stops the process although there may be present plenty of fermentable material in the liquid. The remedy proposed by Dr. Koch evidently belongs to the third class, creating prompt general irritation or febrile action followed by decided necrosis or dissolution of the tissue affected by the bacilli, thereby diminishing their food and carrying away large numbers of them with the debris, but not directly destroying the vitality of the germs. It is apparent that the action of such a remedy might be both safe and efficient in the treatment of external varieties of tubercular disease, as Lupus, etc., but it is equally apparent that in cases of extensive tubercular development in important internal organs as the lungs, brain, and abdominal viscera, very severe or even speedy fatal results might follow the necrosis of so much affected tissue with no ready mode of exit or exfoliation. These inferences from the *modus operandi* of the remedy, have been verified by direct clinical experience as set forth by its author, who properly enjoins the greatest caution in its use, especially in the advanced stages of pulmonary and cerebral tuberculosis. Consequently it is better that the profession generally should wait patiently until the processes of manufacture have been made reliable, and the results of clinical work by competent parties have had time to develop their real value. In the meantime, let every general practitioner endeavor to acquire the utmost skill in making an early diagnosis of tubercular diseases, at which time a judicious use of such hygiene, climatic, and remedial means as are clearly known, will arrest the progress of a large proportion of the cases; and he will be fully prepared to make the most judicious and efficient use of Dr. Koch's remedy whenever it shall become available; for such is the nature of pulmonary tuberculosis, that it is only in the earlier stages of its development and progress that any really curative treatment can be expected to succeed in effecting a permanently favorable result.

In conclusion, I will mention two popular errors, prominent in both medical and general literature, that do injustice to the character of the

profession. The first is, the very common assertion that all great discoveries in the science and art of medicine have met with unreasonable opposition and prejudice at the time, and the discoverers persecuted and sometimes ruined in their practice and professional standing. In my reading of medical history I have failed entirely to find adequate proof of these assertions. Perhaps the greatest discoveries in medicine during the three last centuries, have been the discovery of the circulation of the blood, by Wm. Harvey; the discoveries in the physiology of the nervous system, by Sir Charles Bell and his contemporaries; the discovery of the cow-pox, with the protective value of vaccination, by Edward Jenner; the discovery of anesthesia and its applications in surgery, medicine and obstetrics, by Wells, Morton, Jackson and Simpson; and the applications of the microscope to studies in etiology, histology and pathology in our own time.

Wm. Harvey made his principal discovery concerning the circulation of the blood in 1619, but used eight years more in accumulating proofs of its correctness, and then, 1628, published a full account of it to the world; and instead of persecutions, his report rapidly gained the approval of the learned both in and out of the profession; he was accorded official positions in hospital and college, and only four years later he was made physician in ordinary to Charles I., with whose fortunes he became identified. The King was soon after defeated by the parliamentary forces, and deposed, which caused Harvey to be displaced from his hospital position, but left him still in the college, and with a rapidly increasing reputation. Less than twenty years after he had the gratification of seeing a statue erected in College Hall to his honor, with his important discoveries indelibly inscribed thereon.

Edward Jenner discovered the cow-pox as early as 1770, but spent the next twenty years in patiently studying its relation to sores on the hands of milk-maids and their exemption from small-pox, apparently counseling with no one but his friend John Hunter, by whom he was encouraged. In 1796 he ventured to vaccinate his own son; and in 1798 published a full report of all his investigations. Before the end of the same year his views were practically tested by Mr. Cline, and received the cordial public endorsement of seventy-three of the leading physicians of London. Within two years his report had been translated into nearly every language in Europe, and his views approved and practically adopted by the profession not only in Europe, but also in the Colonies of America. Within the short space of five years he was receiving testimonials in abundance from most of the crowned heads and scientific bodies then in existence. That he was denounced in intemperate language by here and there a medical or clerical crank, is true. And the

same is just as true even at this day, as the sayings and doings of existing anti-vaccination societies prove. But no one would now think of quoting the doings of these societies as evidence that the regular medical profession is either opposed to vaccination or indifferent to the reputation of one of the greatest benefactors of his race.

Indeed, so far from receiving the announcement of new discoveries with prejudice and opposition, by the medical profession, it would be extremely difficult to find a single important new fact, principle, remedy, or mode of practice, fairly published to the world during these last three centuries, that has not been respectfully received, promptly acted upon, and in less than ten years assigned to its proper place with due credit to its author. Instead of delay and prejudice, the principal evils have resulted, as I have previously said, from immature announcements and too much haste in their practical appropriation.

The second popular error consists in presenting the *extravagancies*, both in doctrines and practice, of each medical era, as evidence of the character of the medical men and practice of that time. Every age or generation has its extremists who become extravagant in the practical application of whatever rules or remedies they adopt; and their extravagancies are sure to be recorded on the pages of the current literature, and to be quoted by all subsequent generations as characteristic of that time; while the great mass of active practitioners never copy or follow such excesses. Thus, during the first half of the present century, for every excessive venesectionist like Bouillaud, there were ninety and nine intelligent practitioners who never practiced venesection except in the first stage of acute diseases, and then rarely more than once. And yet, I have not listened to a discussion concerning the practice of that period during the last quarter of a century, that Bouillaud and his few imitators were not quoted as the representative men of the time. The same rule will be found true in regard to the extremists and the conservative masses of the profession in every subsequent era.

The only remedy for these popular and unjust errors is a frequent recurrence to the standard authors of the past generations, or in other words, an honest and thorough study of the history of medicine as a necessary branch of medical education.

THE MEDICAL CLUB OF LOUISVILLE.—At a recent meeting of the leading physicians of Louisville, Ky., it was decided to construct a building, in which meetings of the club are to be held, and in which a medical library is to be located. In its construction every possible convenience will be assured. It is anticipated that this movement will command the generous support of the entire medical profession of that city.

ECTOPIC PREGNANCY. WITH REPORT OF TWO CASES.

Read before the Gynecological Society of Chicago, September 11, 1891.

BY HENRY BANGA, M.D.,
OF CHICAGO.

On June 23, 1890, a lady called at my office complaining of bloatedness, backache, and constipation. She gave her age as 27, was of American birth, had enjoyed perfect health up to her marriage four years ago; pregnant once three years ago, labor at full term, normal. Right after she got up from confinement she had ulceration of the womb, for which she was treated over a year in Milwaukee. It is an exacerbation of this womb trouble (she thinks) that now compels her to consult a physician. Upon examination I found the cervix neither lacerated nor ulcerated. In the region of the right ovary there was a painful swelling; a thorough examination, however, was impossible, on account of the tenseness of the abdominal walls. I told the patient that part of her complaint was no doubt due to constipation, and that I would first try to relieve this and pay more attention to the womb later; I prescribed accordingly. About a week later, on the 30th of June, she again called at the office on account of constipation and intense bearing-down pains. I again examined and found the uterus decidedly larger than normal, the cervix peculiarly soft and doughy; the swelling on the right side of the womb seemed also somewhat easier to be felt. I told the patient I thought she was pregnant, and the bearing-down pains might indicate a miscarriage. She repudiated the idea, as she noticed no subjective symptoms of pregnancy, and as she had always been regular with her periods. She had menstruated last on the 7th of June, and expected surely to menstruate again on the 7th of July.

On July 3d I was called to the patient's house. She suffered excruciating pains, beginning in the lower part of the abdomen and radiating down the thighs; the pains were steady and there were on intermittent, labor-like pains. Enemata opened the bowels, but did not remove the pains, which were only controlled by morphia. There was no nausea, no fever; appetite wonderfully good. In this way she passed a miserable time up to the 7th of July, the date of the next expected menstrual period. For the first time in three years the menstrual flow failed to appear. On the 12th, however, there was a show, and on the 13th she flowed quite freely. Meanwhile I had made up my mind that she was undoubtedly pregnant; and in order to satisfy myself as to what had become of the swelling on the right side, I examined on the 14th. There was no doubt that it had decidedly increased and had pushed the uterus over to the left and somewhat forward. It was exceedingly painful. To all appearances I

had to deal with a case of extra-uterine pregnancy. I thus informed the husband, and we decided to call Dr. Jaggard in consultation.

On the 18th we examined the patient under chloroform, and found the uterus enlarged, especially so in its antero-posterior diameter, pushed forward, and somewhat to the left. The cervix had the soft, doughy touch characteristic of pregnancy. To the right of the uterus, in a somewhat downward and backward direction, an elastic tumor of the size of a child's fist was felt. Between the uterus and tumor there was room enough to put in a finger. Dr. Jaggard confirmed my diagnosis and also concurred with me in recommending immediate operation. This I did at the Michael Reese Hospital, Dr. Jaggard being present, on the 25th of July.

After opening the abdomen the bowels appeared slightly stained with bloody serum. Pushing these back, the whole situation could be taken in at a glance. Having introduced a colpo-uter into the rectum as I am in the habit of doing, in order to lift up small tumors situated deep down in the pelvis, I at once reached the tumor. There was, to the left, the uterus, twice its normal size and very turgid. The left tube, very much hypertrophied, as thick as the index, exhibited large veins. The right tube was still larger; its middle part especially showed an immense hypertrophy of its muscular elements, which spread like a fan over a tumor. The latter was of the size of a child's fist; it was glued by soft attachments to the uterus, the rectum, small intestines, cecum, and right side of pelvis. These adhesions were so loose that they easily broke down under the finger. Very little hemorrhage followed. After thus freeing the bulk of the tumor a pedicle was easily formed. I first ligated the uterine end of the tube, then I secured, by three linked ligatures, the fimbriated end of the tube and part of the broad ligament, including also the ovary. After removing the tumor there was an annoying oozing from a separated adhesion to the rectum, so much so that I decided to use a tobacco-bag tampon with iodoform gauze, after Mikulicz. The patient rallied very readily from the operation. There was considerable bloody discharge through the tampon during the first two days. The tampon was removed on the sixth day. For a number of days the temperature rose to 101° in the evening, which elevation was due to the iodoform as was clearly demonstrated by the prompt return of normal temperature as soon as we began using oxide of zinc and later on balsam of Peru. There is still, on October 26, a small fistula left, at the bottom of which I think a ligature keeps up a little discharge; otherwise the patient is well. She began menstruating, the first time after the operation, on September 18th.

Examination of the specimen showed that it

* November 11th ligature extracted through fistula

was a case of tubal pregnancy. The ovisac proper was situated in the middle of the tube, while the upper wall of the tube—*i.e.*, the part next to the anterior abdominal wall—showed immense hypertrophy of its muscular fibres (they were as large bundles of a strong biceps). The opposite side of the tube was thinned out so much that it seemed as though the ovum was ready to break through, out of the tube, into the cul-de-sac of Douglas. The amnion was intact; it contained about an ounce of fluid, and the fetus well differentiated and apparently about five weeks old. The ovary, which was removed together with the tubes, contained a cyst of the size of a small apple, being filled with a chocolate-colored, thin fluid.

Shortly after the preceding case had left the hospital another was brought in, of which the house physician, Dr. M. Goodkind, has furnished me with the following history: Patient *æt.* 40, menstruated at 14; menstruation every four weeks up to five years ago, when the flow became irregular, sometimes occurring twice a month; generally lasts seven days, without pain and of fair quantity. Patient menstruated last three months ago (May 20th). Married seventeen years; three confinements, all full term, normal labors; eldest child 13 years old, youngest 5. Six weeks ago (July 16th), while washing she experienced sudden and excruciating pains in neighborhood of genitals, causing unconsciousness which persisted for an hour. When she emerged from this condition she described sensations of vertigo, tinnitus aurium, pain, dyspnea, and utter prostration, causing such intense distress that she became incapable of any exertion and took to bed. Accompanying these symptoms she had alternating chills and fever, anorexia, nausea, and vomiting. A week after she began to menstruate slightly, and has done so to date. These various symptoms caused a rapid deterioration in health, and on August 27th she entered M. R. Hospital.

Status præsens: Patient of strong build but extremely anæmic; has a haggard and careworn expression. She suffers with intense bearing-down pains. Abdomen presents a symmetrical enlargement extending from the symphysis to one inch below the umbilicus, of fairly hard, elastic consistence. No fetal sounds.

By bimanual exploration we found the cervix pushed up behind the symphysis by a round-shaped tumor resembling a small head descending down upon the floor of the pelvis. It was impossible to properly locate the fundus uteri, its outlines being lost in the tumor, which extended from the posterior cul-de-sac along the region of the left broad ligament to within an inch below the umbilicus. It seemed to fluctuate, and, in fact, to present all the symptoms of a hæmatocele. I inserted an aspirator needle, but did not get any fluid. The following days the patient had a little fever, the temperature ranging in the evening be-

tween 100° and 102°; the pains were controlled by morphia, but the tumor seemed to rather increase, causing retention of the urine, necessitating frequent use of the catheter. I deemed it necessary to do something radical to relieve the patient, and so I decided upon laparotomy. Our junior gynecologist, Dr. Frankenthal, agreed with me in the diagnosis—hæmatocele, probably caused by the bursting of an ectopic ovisac. September 4th was set for the operation.

After opening the abdomen the omentum and bowels appeared tinged with a peculiar yellow-brown color, which revealed at once the bloody nature of the tumor. The tumor lay hidden under the small intestines, which were easily loosened by the finger and pushed back with a sponge, so that the apex of the tumor was brought to view. After sponge-packing all around it, in order to protect the abdominal cavity against an overflow of possibly poisonous liquid, I first tried to aspirate; but, failing to get any fluid, I cut into it with a knife, making an incision wide enough to admit a half hand. It contained black, semi-coagulated blood, which I scooped out with the hand. Thus far I thought I had to deal with a simple hæmatocele, and that the uterus lay pushed over to the left side. While manipulating to get the last coagula out I loosened what I considered to be the womb; it proved to be a hard, solid coagulum, which was hanging attached to a few loose shreds from the left horn of the uterus. The uterus proper I found in the median line and of normal size. After thoroughly cleansing the abdomen and the sac, I stitched the latter to the peritoneum and packed it with iodoform gauze. The patient rallied nicely from the operation. On the second day, however, the temperature went up to 103°, the abdomen became tympanitic, pulse weak, 130. Gases had failed to pass so far, in spite of laxatives, rectal tube, and turpentine enemata. We really thought the patient in great danger of beginning peritonitis, and in order to give her a chance we took her at 9 o'clock in the evening to the operating room, in order to relieve a possible retention of the wound secretions. While she was on the table, and before I had done any mischief to the wound, the first flatus passed *coram publico*. From that time on she began to feel better. She is still in our ward and has no fever; the wound discharges very little, and is becoming smaller from day to day.

In this case tubal pregnancy had occurred, the ovisac burst, first causing hæmato-salpinx, then hæmatoma of the broad ligament, finally tearing and disintegrating the whole tube, the remnants of which were hanging down in shreds from the left cornu uteri. Later on there was renewed hæmorrhage into the pouch of Douglas, causing hæmatocele. The sac, which I stitched to the abdominal incision, was organized blood, not

peritoneum. The original ovisac, represented by the hard coagulum covered with villi, lay inside of the hæmatocele.

I now wish to add a few general remarks:

1. *Diagnosis of Ectopic Pregnancy.*—It must be easy to make a correct diagnosis after the fourth month and before rupture of the sac, because we feel the living fetus or hear the heart sounds. Before the fourth month there might sometimes be a doubt left, especially if the physician sees the patient perhaps only once, or if he be unable to get an intelligent history. Besides the well-known and generally accepted signs of pregnancy (subjective and objective ones), I would derive the most valuable help, in making a diagnosis, from a close history. There will always be some *irregularity* in the menstrual flow—either cessation or too early recurrence of the periods—while formerly the menstruation has been regular. This irregularity resembles very closely the flow in a case of abortion. Another valuable symptom will be intense, excruciating bearing-down pains, mostly one-sided. These are not labor-like pains, but are more steady. They are no doubt caused by distention of the tube, due to the rapid growth of the tumor. If we add to this the objective symptoms—the enlargement of the uterus, that characteristic doughy touch of the cervix, the presence of a gradually increasing tumor somewhere in the region of the broad ligament—then I think there should be sufficient reason to warrant the diagnosis of ectopic pregnancy. My first patient illustrates this symptomatology most conclusively. She is a woman who has always menstruated regularly to the day. Fourteen days after her last menstruation she begins to experience intense bearing-down pains, starting in the right hypogastric region; then, for the first time in three years, she goes over her time six days; then a free flow sets in for ten days, shreds of decidua pass. With all that there is no fever and no other cause to explain the pain. By digital exploration we find an enlarged uterus giving that characteristic doughy feel of pregnancy, together with a steadily increasing tumor situated near the womb in the region of the broad ligament. There was, however, one classical symptom of pregnancy wanting, namely, the patient herself had not the slightest idea of being a gravida.

Now, how about the diagnosis of rupture of the ovisac? Those cases constitute two different classes, namely: (a) Rupture causes acute internal hæmorrhage. Now, since there is hardly any other trouble but ectopic pregnancy causing internal hæmorrhage, we may diagnose it at once if a patient shows the well-known symptoms of acute internal hæmorrhage. (b) Rupture causes peritonitis, sepsis. If a patient had not been under observation before the accident, it might often be impossible to differentiate a ruptured ovisac

from a ruptured pyo-salpinx, ovarian cyst, or the like. About hæmatocele see further on.

2. *Anatomy.*—You know that Lawson Tait claims that the different varieties of ectopic pregnancy described in the text books are mere theoretical classifications, and that all cases are originally tubal, becoming ovarian, interstitial, or abdominal only after rupture of the tube and migration of the ovum to a new resting place. The simplicity of this theory recommends it. All the recently published cases were tubal pregnancies, as were the two cases related this evening. The first case also clearly demonstrates by the thinning out of the tube the possibility of an ovum slipping out of such an opening.

3. *Frequency.*—Late publications go to show that ectopic pregnancy occurs much more frequently than we have generally thought, a great number of cases of so called *hæmatocele retro-uterina* and hæmatoma of the broad ligament being nothing but cases of ruptured ectopic pregnancy. Martin, Olshansen (of Berlin) have described many such cases. Sure enough, they never found the fetus, but were able in every instance to demonstrate the true nature of the disorder by the presence of decidua cells. Orthmann (who published Martin's cases) says that if in a hæmatocele we find an organized, well defined coagulum, we may feel sure that this coagulum was originally an ovisac. Upon its microscopical examination we will find villi or decidua cells. Our second case wonderfully corroborates this statement. *In situ* yet of the torn and bursted left tube, and surrounded by the semi-coagulated blood accumulated in the hæmatocele sac, we found a coagulum of the size of an apple, being covered with villi and enclosing the shrunken remnants of an otherwise well-differentiated fetus.

4. *Predisposition to Ectopic Pregnancy.*—It is worth while to repeat here that the first patient had been ailing for years (after her first confinement) with pains in the right ovarian region, and that an ovarian cyst of the size of a small apple, containing thin, chocolate-colored fluid, was removed together with the ovisac, right ovary and tube.

5. *Treatment.*—There is hardly any possible difference of opinion about what to do if a physician is called to treat a patient showing the symptoms of a bursted ectopic ovisac. We have, of course, to perform laparotomy at once—in the one case to stop an otherwise fatal hæmorrhage; in the other case to remove decomposed matter which, if left in the abdominal cavity, will undoubtedly set up fatal peritonitis. (See also the remarks about hæmatocele.) What shall we do with a case where the sac is still intact? Let us first ask what will become of the patient if left to her fate. The sac might burst at any time, thus giving the patient a chance to die either from hæmorrhage or from sepsis; or if she should

escape both, and the fœtus undergo mummification (lithopædion), she might, after years of suffering, see the fœtus make its way out of the abdomen by perforating bladder, vagina, and rectum. Such being the case, I think the best way to deal with any case of extra-uterine pregnancy is to extirpate the ovaries as soon as the diagnosis is made. For, even if we succeed in killing the fœtus by electricity, aspiration, or injection of morphine, we are by no means sure that no sepsis or hæmorrhage will follow, or that, years after, a lithopædion will not cause trouble necessitating an operation.

In an early month the operation will amount to nothing more but a laparotomy for a small ovarian tumor or salpingitis.

Thomas has warmly advocated the use of electricity, not only with a view to killing the fœtus and waiting for its resorption, but also with a view to arresting placental circulation, thereby minimizing the danger from hæmorrhage in a subsequent laparotomy. This would seem a very good plan if the action of electricity were sure; but since it is not, it seems more rational to operate at once and not allow the placental circulation to increase by a delay due to futile efforts to arrest it. In my first case Dr. Jaggard and I discussed the propriety of a trial with electricity, but we decided to gain time over an increase of the placental circulation by immediate operation, and we really had no difficulty in controlling hæmorrhage.

However, as gestation progresses the danger from hæmorrhage increases. There being no contractile tissue to stop the gush of blood issuing from the placental insertion, it is of the greatest importance not to disturb the placenta. In such a more advanced stage of ectopic gestation where rupture occurs less frequently, I would try Thomas' plan with electricity as the first preparatory step to a later laparotomy. In case pregnancy, for some reason or another, has been allowed to go on to near full term, the child has also some claim for consideration. Here, in order to save a viable child, we might put off laparotomy until labor begins, being ready, however, to operate at any time if symptoms of rupture of the sac should demand it. The safest way to treat with the placenta in such a case seems to be not to attempt to detach it, but stitch the sac to the abdominal wound, pack with iodoform gauze, and wait for spontaneous loosening of the after-birth.

In case of hæmatocœle the proper treatment would be to first wait for natural resorption of the bloody effusion; second, aspiration; third, opening through the pouch of Douglas, if the tumor does not reach high enough to allow it to be sewed to the abdominal walls; fourth, laparotomy, if the tumor touches the anterior wall of the abdomen. Laparotomy seems the most rational procedure, because it allows us to properly locate

the extent and surrounding parts of the hæmatocœle. Whenever incision is resorted to, the opening should be made wide enough to get all the coagula out. In the last case I doubt whether it would have been possible to get the large coagulum out through the vaginal opening.

MEDICAL PROGRESS.

Therapeutics and Pharmacology.

A NEW DISINFECTANT.—The list of disinfectants that has grown so rapidly of late, has received a further addition under the name disinfectol (*desinfector*). According to LOWENSTEIN (*Revue Hebdomadaire de Thérapeutique*) it consists of a combination of iodine phenol and different hydrocarbons. It is a liquid of considerable consistence which in odor and properties approaches closely to creoline, of alkaline reaction and miscible with water in all proportions, forming a clear or grey emulsion according to the proportions employed. M. Beslin in testing the antiseptic value upon feces found that in the proportion of .5 it disinfected an equal volume of fecal matter in eighteen hours. In the strength of 10 per cent. an equal volume of feces were completely sterile at the end of fifteen minutes. The bacillus typhoidal was destroyed by a two per cent. solution. The five per cent. solution was equal in disinfecting power to one of 12.5 of creoline, hydro-chloric acid 33, carbolic acid 5, sublimate 2.

RAPID EFFECTS OF KOCH'S REMEDY IN LARYNGEAL PHTHISIS.—PROF. OPPENHEIMER, of Heidelberg, reports the following case (*Deutsche Med. Wochenschr.*, December 4th, 1890):—The patient was a woman, aged 28, who had been ill for two years. She had infiltration of the right upper lobe, dulness at the left apex, bronchial breathing, moist rales, and bacilli in the sputum. Since September of the present year she had continual fever, with evening exacerbations and night sweats. She complained of irritation in the throat, which brought on paroxysms of coughing from six to eight times a day, and made her vomit most of her food. This, and the hoarseness of her voice, made Professor Oppenheimer suspect that the larynx was implicated in the disease, but laryngoscopic examination was impossible, owing to the irritability of the throat, which even the free use of cocaine could not subdue. She was very weak when Koch's fluid (1 milligram) was injected for the first time on November 22nd. Reaction was slight; the coughing and vomiting continued during the day as before. On November 23d she was again injected (1 milligram). Nine hours afterwards the temperature rose from 37.6° to 39° C. During the following night there

was much sickness, with headache, and coughing; expectoration was diminished. On the 24th 1 milligram was again injected. In about six hours the temperature again rose to 39° C. and the patient complained of giddiness, shortness of breath, with a feeling of contraction in the throat; there was no difficulty in swallowing, the cough was less, but the voice was somewhat hoarser than before. With great difficulty a laryngoscopic examination was made, and it was seen that on the fore part of the right vocal cord there was a bluish red excrescence of the size of a millet seed, the rest of the cord being greyish red in color, but otherwise normal. The ventricular bands and arytenoid cartilages were normal. On the following day the excrescence had disappeared, and only redness and slight swelling of the vocal cord remained. From that day the paroxysms of coughing and vomiting entirely ceased, and up to the date of the report (December 1st) never recurred. The only thing the patient complains of is slight pain in the region of the larynx, which comes on from eight to ten hours after each injection, and lasts from three to four hours. No improvement has, however, taken place up to the present in the lung symptoms.—*Brit. Med. Jour.*

PYOKTANIN.—PROF. STILLING has given, in three recent numbers of *Merk's Bulletin*, a valuable report upon pyoktanin. He summarizes its qualities in the following terms: 1. Pyoktanin is an antiseptic surpassing all remedies of this kind heretofore known in regard to both development-arresting and germ-destroying effect. The two strongest antiseptics employed in medical practice are sublimate and iodoform. The bacteriological researches have shown blue pyoktanin to be about three times as strongly antiseptic towards anthrax bacilli as sublimate is, and to be quite as efficacious as sublimate towards the staphylococcus aureus; while the inefficacy of iodoform towards pus cocci is a generally acknowledged fact. 2. Pyoktanin is an absolutely non-toxic substance. Herein it possesses a most desirable advantage over all the other antiseptic remedies, whose toxic effects are known to hold, generally, a pretty direct ratio to their anti-bacterial action. 3. In consequence of this non-toxicity of pyoktanin it is a matter of indifference in very many cases whether somewhat weaker or stronger solutions, or even the pure drug, be employed. (This principle is good pre-eminently in the treatment of wounds and ulcers; but of course it cannot apply to ophthalmology). 4. Pyoktanin does not coagulate albumen—a negative quality of high value physiologically, which pertains to not a single one of the antiseptics heretofore known. 5. Pyoktanin possesses an extremely high degree of diffusibility; it permeates the interior of the eye like atropine, and acts similarly in other tissues. As far as surgery is concerned, Professor

Stilling believes that his researches have demonstrated that suppuration can be cut short by bringing pyoktanin into intimate contact with the suppurating tissues. After giving details of his experience of this substance in many branches of ophthalmological work, he concludes by remarking that even here, though somewhat less so than for general medicine and surgery, the entire matter is still *in statu nascendi*.—*Lancet*.

Medicine.

ARSENIC AND PEMPHIGUS.—MR. JONATHAN HUTCHINSON's address in the Dermatological Section of the British Medical Association referred to the opportunities offered in connection with skin diseases for the study of general therapeutics and for observations on the action of drugs. As reported in the *Lancet* he offered a striking illustration of this proposition in the behavior of arsenic, which has long stood in the forefront among those remedial agents regarding which have been collected many important and even astonishing facts. And he adds: "There is no more wonder-producing fact in the whole range of therapeutics than the ease and rapidity with which arsenic contracts and cures common pemphigus. There may occasionally be exceptions, but, as a rule, not another bulla appears after that remedy has been commenced. We have, indeed, ceased to see any cases of chronic pemphigus ever since this fact has been made known." There, however, he complains, the knowledge ends, for no one has yet been able to discover how the drug acts, and we are still ignorant also of the real nature of the malady that so generally succumbs before that drug. It does not always cure the malady but it always changes it for the better. He who would completely unravel the mystery of how the bulbous eruption comes to be healed, and the scaly one changed, how the skin may be made to clear up in one case or to become muddy and brown in another, how peripheral neuritis may be produced to end finally, unless prevented, in some severe form of paralysis and death, and how in rare instances the nutrition of the skin may be so influenced that keratosis and even cancer may be the result, will certainly find that he has his work cut out for many years. Only the foundation of the subject has as yet been laid.

TREATMENT OF DIABETIC COMA.—SCHMITZ (*Berliner Klin. Wochenschr.*) recognizes two distinct forms of diabetic coma. In one there is heart failure and in the other a toxæmia. In the first class of cases we have a diabetic who is often fat but whose muscles are soft and flabby, the gait is insecure, and breathlessness is produced by slight exertion. In these cases the heart, like other muscular structures, is poisoned by the excess of sugar in the blood. After a time distinct

heart failure appears, manifested by a quick, feeble pulse, obscure or absent first sound, with increased area of dullness at the base. The heart's action finally becomes weaker, somnolence comes on and the heart may strike work suddenly or gradually. The treatment of these cases should be an avoidance of all undue over-stimulation and over-taxing the heart. A nutritious and easily digested dietary; of course, the general diabetic condition must not be overlooked. In acute cases, where cardiac failure is imminent, the patient should be kept in a recumbent position and heart tonics administered. One of the best is black coffee together with musk and camphor hypodermically if there is nausea. The greatest danger lies in allowing the patient to get up too soon. He should be kept on his back until the first sound of the heart becomes clear and distinct.

The second form of diabetic coma he regards as an acute auto-infection named, but not correctly, acetememia. The symptoms principally relate to the digestive tube, lack of appetite, eructations of foul gases, constipation usually, but sometimes diarrhoea, together with heaviness and drowsiness. This state may last for some days, but eventually the patient becomes more and more stupid. The temperature rises and the pulse increases in frequency, colic pains are present, frequently accompanied by vomiting of dark or greenish colored fluid. The pupils, as a rule, are contracted and react but feebly to light. Towards the end violent clonic convulsions appear, deep coma supervenes to be followed by death.

The colic, high temperature and *clear heart sounds* serve to distinguish this last from the first variety. The writer thinks that this poison is absorbed from the intestinal canal, and recommends that in all of these cases free purging with castor oil should be resorted to. It makes no difference whether diarrhoea is present or not, if the oil is given a number of dark foul stools result, which are quickly followed by an amelioration in all of the symptoms. The author gives an account of eight cases of equal severity, in four of which oil was given and in four not;—the former all recovered, while the latter all died.

Surgery.

BRAIN SURGERY.—WALKER (*Med. and Surg. Reporter*, Vol. Lxiii, No. 8, p. 213) reports eleven cases of brain surgery.

There were two cases of compound fracture of the skull in which fragments of bone were driven through the dura mater into the brain. Trephining was performed and the fragments of bone were removed, with recovery in both cases. There were three cases of fracture of the base of the skull accompanied by intracranial hæmorrhage. The indications for trephining were the pressure symp-

oms. Two of these cases recovered. There was one case of intracranial hæmorrhage without fracture. Trephining was performed six days after the injury, and 5 ozs. of coagulated blood were removed from between the skull and dura mater. The patient recovered.

There were two cases which received no benefit from operation. One was a case of supposed ancient intracranial hæmorrhage and the other a case of epilepsy.

The lateral ventricles were tapped for effusion in one case. The method of operating was that proposed by Keen. The trephine was placed $1\frac{1}{4}$ inch behind the meatus and $1\frac{1}{2}$ inches above Reid's base line; the puncture being made toward a point $2\frac{1}{2}$ inches directly above the opposite meatus. A considerable quantity of serous fluid was removed in this way; the patient, however, died in seven hours. The reporter is of the opinion that death was due to compression from hæmorrhage, which was caused by the operation. No autopsy was made. There was one successful case of trephining for epilepsy, which followed traumatism four years previous to operation.

Finally, there was a fatal case of operation for brain tumor. The tumor was not discovered at the operation. The autopsy showed it to be a cyst which had its origin at the apex of the petrous portion of the temporal bone.—*Amer. Jour. Med. Sciences.*

Obstetrics and Diseases of Women.

KINKEAD ON RUPTURED PERINEUM.—The author records three cases of ruptured perineum which occurred in his practice, in spite of every caution he took to prevent the mishap; and he strongly urges that these cases should be attended to at once, and not allowed to heal by chance. The author states that the neglect to repair arises from two causes: 1. The notion that if the laceration is not extensive, union may take place by means of rest, position, and cleanliness; and if extensive, so that the rectum is involved, it is useless to suture the wound, as union is not likely to take place. 2. The idea that laceration of the perineum is an indication of incompetence or neglect, and likely to prejudice the patient against the practitioner. Dr. Kinkead describes three cases, in which he shows that the rupture was extensive in each case, in spite of great caution, and perfect union occurred after suturing the wound with deep sutures, though in one case the rent extended into the anus, and for an inch up the rectum. Whether it be that higher education and social progress produce larger fetal heads, or render the perineum more friable, the author is unable to say, but he states that he finds it more impossible to preserve the perineum intact than he did when he began practice.—*London Medical Record.*

SATURDAY, JANUARY 24, 1891.

NEW SOCIAL REMEDIES.

The physical and medical side of pauperism, criminality, and associate evils have received a great uplift in GEN. BOOTH'S work, "On Darkest England and the Way Out."

The purpose of this work is to bring out the fact, that one-tenth of the London population are paupers, criminals, lunatics and outcasts generally and are called the "submerged tenth"; also that all remedies and means to reach and correct this evil are failures unless especially addressed to the physical side. Another fact seldom realized, yet terribly true, is that pauperism and its associate disorders are indigenous, and when once they take root in a town or city, reproduce themselves through heredity, surroundings and conditions of life, with a persistence that defies all missions, churches and free charities. The so-called charities in most cases increase the very evils they are intended to relieve. This is illustrated in many of the dispensaries so generously supported by physicians, that are literally schools of pauperism.

GEN. BOOTH'S "way out," or remedy, is to draft out this terrible army of defectives, in work-houses established in the worst centers. These places are to furnish good rooms, food, clothing and mental change, in return for services of some kind. After residence and training here they are to be transferred to form colonies, with larger opportunities for more comfort and better living and a chance to make a surplus beyond food and clothing. From a longer residence here they are

to be sent to foreign colonies, and helped to make home centers for themselves. These foreign colonies to be cooperative and care for those who are unable to be independent; thus these parasites of society are to be lifted out, trained and taught to work and give some return for food, and all the comforts of a better home. The first great lesson is to be independent, and to earn under the direction of others, the joys of better conditions of life and living. In this way a large majority of the defective paupers and criminals who are prevented from rising by surroundings and conditions of life, are lifted out of their breeding places, and placed in new mental and physical environments, and trained to appreciate this change, and be restrained from falling back again.

By this appeal to the physical side, the way to the higher controlling forces is reached, and the man who would have become a burden becomes a producer. The common methods are to break up pauper centers and scatter the inmates, who with unconscious certainty proceed to form other and more dangerous centers. This plan is to draw out such defects and give them a chance to rise to better conditions of life. GEN. BOOTH calls for a million dollars to begin this scheme, in London, a third of which is already subscribed. This indicates that the public mind responds quickly to methods that are rational and along the line of scientific research.

The new criminalology and sociology of evolution sustains the practical character of this plan. This work is exciting most intense interest among all classes of laymen, but beyond this it has a medical aspect which has not been noticed yet. The London paupers, criminals and outcasts are growing up in all our large towns and cities, and are identically the same classes, only varying in degree. When these classes are studied scientifically they are found to follow certain lines of causation, and conditions of heredity and environment, that can be traced and predicted with absolute certainty. They are the products of heredity and physiological development and non-development, that in certain conditions and surroundings of life will merge into the criminal pauper and defectives, and become the dangerous classes.

So far all the studies of these cases have been by theologians, lawyers and philanthropists, entirely from a theoretical standpoint, and of course

the remedies have been strangely empiric and largely failures. No clinical study of these cases in their haunts, or in reformatories or prisons has been made. Only a few fragmentary articles have appeared. One or two reform prisons have demonstrated the great changes that will follow physical training and culture, and the possibility of curing criminals and sending them back to society useful law abiding citizens. These irregular studies show that all these so-called dangerous classes are bred and cultivated from germs and germ soils, that they grow up and develop in conditions that can be recognized and prevented. The educated physician is the most competent of all persons to study and point out the true remedies. GEN. BOOTH's plan recognizes this fact in the materialistic character of the means for relief.

This entire subject of the pauper and dangerous classes is along the line of sanitary science and preventive medicine. Here the physician rises above the lower level of drug dealing, and becomes a student and teacher of the laws and forces which control the evolution or dissolution of individual life. What GEN. BOOTH proposes to do in London may not be carried out practically, but it suggests possibilities that can be put in operation in every city in the country. It suggests new fields of medical research and medical activity, that will close free dispensaries and dangerous charities, and change the police courts and jails from training schools of crime to homes of growth and preparation for better life and living.

Medical men in every community must study these dangerous classes, and advise and direct the remedies for restoration and prevention. A practical knowledge in this direction will be liberally rewarded by the public, and raise the physician to the realm of leadership in a new field of work for humanity. Each new advance of scientific research reveals the possibility of escape from epidemics and widespread fatal diseases, and every new study of these dangerous classes reveals certainty of finding means of prevention and cure. Pauperism including criminality, and all the associate defects, are medical problems to be studied from the physical side, and treated by physical remedies, not drugs, but by the application of laws and forces that will help the victim back to health again.

Everywhere there are intimations of a great

revolution in our knowledge and treatment of these cases. The losses and burdens they entail on every community bring the study of remedies and means of prevention into great prominence, and calls for the best talent of the profession in every section.

THE COMPOSITION OF KOCH'S LYMPH.

PROFESSOR KOCH has made a third report of his work under date of January 15. His reasons there given for withholding from the public to the present time the exact composition of the fluid used in the treatment of tuberculosis, should be satisfactory to the medical profession. The modest manner in which he now refers to his previous labors, and the methods employed by which he has reached his present conclusions, commands approval, and the unreserved manner in which he now gives to the public the results of his labors must surely disarm those who were disposed to criticise the withholding of his discovery from an exacting and impatient multitude.

"The remedy," says PROFESSOR KOCH, "which is used in the new treatment, consists of a glycerine extract derived from the pure cultivation of tubercle bacilli."

This extract contains not only the effective substance derived from the bacilli, but such other substances, consisting of salts, coloring material and extractive matters, as would be soluble in a fifty per cent. solution of glycerine. Their elimination is of no practical importance, since they exert no essential influence upon the human organism. Combined with other extractive material the effective matter is precipitated by alcohol, in which it is insoluble, and can be isolated from other substances in a comparatively pure and concentrated form and with increased potency.

Regarding the composition of the effective substance, as he terms it, PROFESSOR KOCH says that for the present only surmises can be entertained. He believes it to be derivative from albuminous bodies and having close affinity to them. That it does not belong to the group of toxalbumens, he argues from the fact of its tolerance of high temperature and of its behavior in the dialyser. So far as can be estimated, the percentage of the active principle in this solution is exceedingly small, being rated at a fraction of one per cent. It is evident that we here have to do with a remedy which, considering the effects which it

produces, is far more potent than any drug hitherto employed.

Various views are entertained as to the manner in which the substance produces its effects.

It is known that tubercular bacilli, when growing in living tissues, produce substances which affect unfavorably and in concentrate form produce necrosis of living tissue. In this necrotic tissue the bacillus fails to obtain its needed nourishment, ceases its development, and sometimes dies.

Thus the very environment of the bacillus is inimical to its development and multiplication. If now a substance be introduced that can develop the necrotic environment still further, and limit the possibilities of its growth, by so much the more will its limitation and destruction be assured.

It may be as yet impossible to explain the manner in which this remedy exerts its specific influence upon tuberculous tissue. Nor can we yet understand the remarkable rapidity with which its effects are produced. Nor does time yet suffice to determine as to the permanency of alleged favorable results. Instances are cited where the tubercular bacilli disappeared from the sputa of patients while under treatment, and at the end of three months had not reappeared, the patients in the meantime improving in health, the physical signs of phthisis having disappeared.

EDITORIAL NOTES.

DIPHTHERIA AT HALIFAX, N. S.—The *Maritime Medical News* for January comments editorially on the high mortality of diphtheria, during the last fifteen months, at Halifax. The exact amount of the death-roll cannot be stated, but the editorial writer estimates that as many as 250 deaths were due to the cause named, and the end is not yet. These deaths were mostly among children, causing an abnormally high infant mortality. And yet Halifax has very much in its favor as regards its geological and geodetic conditions, washed by the sea on every side, and furnished with a water-supply that is above suspicion. But the city is uncleanly within, as was shown by an inspection made last summer, under pressure of public opinion and against the opposition or inertia of a cumbersome health machine. This inspection revealed premises innumerable reeking with domestic filth, saturated and overflowing cesspits,

uncleaned streets, uncollected garbage and an inadequate sewer system. The economic loss to the city has already been great, as the sensitive tide of summer travel has already begun to be diverted by the impression made by the bad bills of health shown by the city. The Board of Health is lacking in its proportion of medical men of alertness and modern training.

THE OVERWORKED PHYSICIAN'S LUNCHEON.

—Dr. Allan McLean Hamilton contributes to the *Dietetic Gazette* some dietetic suggestions in nervous and mental diseases, one of which will interest all those busy practitioners who give themselves no time for a midday repast. His advice would be to lay in a goodly supply of fresh almonds, and to have some of them constantly within reach and to eat freely of them during the spare moments. He writes as follows:

Acting upon a hint given by my friend, Dr. Lauder Brunton, I have directed some of my patients to eat freely of fresh almonds, which are rich in oil and exceedingly nutritious, containing as they do 54 per cent. of fixed oil. According to Pavy they contain 2.67 of nitrogen and 40 per cent. of carbon. It is a custom of Dr. Brunton and several other London physicians, when hurried and tired after their morning consulting hours, to make a luncheon simply of this kind. In cases of diabetes, when digestion is not too weak, it will be found that biscuits of almond flour are exceedingly nutritious and palatable and may take the place of gluten bread.

POETRY ABOUT A MILWAUKEE SURGEON.—A little versification now and then is relished by the sternest of medical men, especially if it be about Professor Senn. Dr. G. Dewey, a Mis-sourian poet, has composed the following lines regarding specialism in medical practice:

"The body has been parcelled out.
For doctors' benefit, no doubt,
Divided up so very nice
That every one can get a slice.
To one they gave the fingers, one the toes,
Another gets the eyes and nose;
A third, more greedy for his part,
Has gobbled up the lungs and heart.
For his untiring, ceaseless pen,
They gave the pancreas to Senn."

MEDICAL PRACTICE IN MINNESOTA.—The results of seven years operation of the Medical Practice Acts in that State have been to reduce the proportion of physicians to 1 in 1,250 persons; whereas it formerly was 1 in 650. Some hundreds of pretenders have been forced to quit the State, and have gone into Michigan and other unpro-

tested States. The present examination act has been in force three years, and in that time only 205 candidates have presented themselves for examination, of these 77, or 36 per cent., were rejected.

EARTH-WORMS AND AFRICAN FEVERS.—The *Kew Bulletin* in an article on the work of the earth-worm in the coast-regions of Western Africa, says that there is an unmistakable comparative freedom from dangerous malarial fevers in the country called Yoruba land, and that many there believe that this freedom is due, in part at least, to the great activity of earth-worms in ventilating the soil and in bringing to the surface the earth in which the malarial germs live and breed. The quantity of soil thus brought to the surface yearly is enormous; but whether or not the diligence of the earth-worms of Yoruba is greater than in adjoining territory, that is smitten with the malarial fevers, is not stated. We are left to infer that it is.

KOCH'S NEW LABORATORY.—The government at Berlin has ordered the construction of a new institute for Dr. Koch. It is to include a sanitarium as well as scientific institution; in the former all required cases of infectious diseases will be cared for and treated under the direction of Koch, the human test-cases in conformation of his researches; in the latter the usual laboratory investigations in bacteriology and other preventive methods, both in old and new directions. Professor Koch will be the director of the institute, with two heads of departments under him and twenty or more practical assistants. An adjunct sanitarium, for the benefit of the poor of the city, has been promised by a private citizen, at a cost of \$200,000. The sanitarium, to be constructed by the government, will have a capacity of 150 beds. Dr. Brieger has been named as the probable first director of this department.

GENEROUS GIFT TO A PENSION FUND FOR NURSES.—The family of the late Junius S. Morgan, formerly of Hartford, Conn., has presented the National Pension Fund for Nurses, England, with over \$38,000 to supplement a collection made by the nurses among themselves, amounting to about \$12,000, this being their spontaneous tribute to the memory of their departed benefactor. This fund will bear Mr. Morgan's name, as a part of the benevolent endowment for the bene-

fit of nurses, which already amounts to \$200,000. Mr. Morgan, during his lifetime, had taken a warm personal interest in the movement and had subscribed liberally, not less than \$50,000, for its encouragement.

PROPOSED MEDICAL LEGISLATION IN MICHIGAN.—At the last annual meeting of the Michigan State Medical Society, a committee of nine of its representative men was appointed to formulate appropriate measures and to influence the profession in the State to secure from the incoming Legislature—"the enactment of just and wise measures, calculated to elevate the standard of medicine in Michigan, and to protect the people from the cruel and dishonorable practices of ignorant and unscrupulous pretenders."

At the meeting of that committee recently held, the conclusions reached were as follows:

1. That the objects to be sought in a medical law were three-fold: preliminary training, professional training, and the enforcement of these requirements.
2. The securing of these objects by a legal organization of the entire medical profession of the State under legislative authority—by means of a legally constituted council by whom those beginning the study of medicine shall be examined with reference to preliminary education, and by whom alone a license to practice medicine in the State shall be issued, and that no other diploma shall entitle the holder to practice in the State.

We confidently believe that if the men who have this matter in charge shall secure the legislation they desire that Michigan will stand in the foremost rank of States as regards the quality of its medical service.

THE KOCH TREATMENT IN THE POST-GRADUATE MEDICAL SCHOOL, CHICAGO.—During the past week the Koch lymph treatment was successfully instituted at the Post-Graduate Medical School of Chicago. This institute, through Dr. Robert H. Babcock, has also fitted a room with all the necessary appliances for the treatment advised by Dr. Shurly of Detroit. Several patients are under treatment by both methods and careful notes are taken of the progress in each instance with the idea of comparing the relative value of the two methods.

TOPICS OF THE WEEK.

THE REVIEWER IN 1831.

The following are a few samples of what reviewers had to say about books in 1831:

"So many plates, etchings, lithographs, and copper-plates bestrew our table that we scarcely know whither to turn to avoid them. Every day sees the birth of some production. If the public buy them all then happy are the authors." This might apply to 1891, as well as the following: "Within the last few years compilations, systems, manuals and guides of all descriptions for the use of students, young and old, have multiplied beyond enumeration. If mind is on the march it is encumbered, like our English armies, with a monstrous quantity of baggage and camp followers."

What would the reviewer have said if he had been spared to the *fin de siècle*. The quotations we have given only lament the quantity of books: the following extract might have been penned to-day: "To those who have made themselves intimate with the medical literature of the last thirty years, and have traced with care the progress of its advancement in some departments, and the cause of its decline in others, nothing can have appeared more amazing than the unphilosophical, unconnected trash which has been teeming in volumes of every size from the medical press of this country. A few observations most hurriedly made; a few new fancies most rudely arranged; or, if you will, a few facts carefully collected are laid down as the framework of a momentous publication, in which general systems are dissected and condemned, preceding authorities are swept into annihilation by broad and dogmatic assertions, and a new creed is proposed for adoption which contests not only its superiority over all that has gone before, but its perfect adaptation for all future ages, nations and constitutions." The extracts are from the *Medico-Chirurgical Review*, 1832, p. 30, and evidently the state of the profession fifty years ago, as regards the production of books, was as bad as it is now.—*Provincial Med. Journal*.

DEAFNESS FOR HIGH NOTES

Mr. Edwin Cowles, editor of the *Cleveland Leader*, who died last March, had a peculiar form of deafness. He never heard the sound of a bird's note, and until he grew to manhood he always thought the music of the bird was a poetical fiction. "You may fill the room with canary birds," he once said, "and they may all sing at once, and I would never hear a note, but I would hear the fluttering of their wings. I never heard the hissing sound in the human voice; consequently, not knowing of the existence of that sound, I grew up to manhood without ever making it in my speech. A portion of the consonants I never hear, yet I can hear all the vowels. About a quarter of the sounds in the human voice I never hear, and I have to watch the motion of the lips and be governed by the sense of the remarks in order to understand what is said to me. I have walked by the

side of a policeman going home at night and seen him blow his whistle and I never could hear it, although it could be heard by others half a mile away. I never heard the upper notes of the piano, violin, or other musical instruments, although I would hear all the lower notes."—*Cleveland Med. Gaz.*

THE OWNERSHIP OF THE PRESCRIPTION

This question has been settled by law in New York, Massachusetts, and a few other States. They all give the prescription to the druggist. Some time ago a judge of a court in Berlin, Germany, gave a similar decision. The text of the decision from the judge of the supreme court of one of our States is as follows: "The question before the court seems to be very simple, indeed. A patient applies to a physician and receives from him certain advice, for which he tenders a fee. The physician hands a piece of paper to the patient, purporting to be a written order for certain goods called drugs, which order is filled by a merchant or apothecary. The payment of the fee and the delivery of the goods or drugs, terminates the verbal contract, and the druggist keeps the prescription as an evidence that the contract has been fulfilled, as far as he is concerned. The druggist can, if he so please, on his own responsibility, renew the drugs, for he is but a merchant, and has a perfect right to sell drugs to any one and in any shape. He need not keep the prescription, nor is he bound to give a copy, but should error occur, he has no protection in case of suit."—*The Pharmaceutical Era*.

THE TEN COMMANDMENTS OF ABDOMINAL SURGERY.

1. The arrest of hemorrhage.
2. The avoidance of mechanical irritation.
3. The guarding against infection.
4. The proper apposition of the edges of the wound.
5. The provision of necessary drainage.
6. To apply gentle pressure to prevent exudation.
7. To give perfect physiological rest.
8. To secure the best possible position of the parts to promote comfort and healing.
9. To provide for hygienic surroundings.
10. To attend to the patient's general health.

—*Dr. Griffiths*.

A NEW SOCIAL DANGER

Opponents of dancing have had a somewhat novel argument suggested to them. Some person whom we cannot but regard as over-cautions has discovered that even the drawing-room carpet is the home of dangerous microbes, and must not be disturbed, lest the infective swarm should arise and poison the atmosphere. With every allowance for the unknown components of dust, the objection is, in our opinion, certainly as whimsical as it is probably original. Such regular cleansing as a carpet undergoes ought to free it from any seriously morbid influence, the more so that a dancing room is less than any other exposed to such mischievous agency. Far more real is the disqualification from which this otherwise healthy form of amusement has always suffered in the opinion of medical men in consequence of its customary methods. The excessively late hours, the indigestible suppers, the needless glass of wine, the close

heated air, and the frequent after chill, though by no means essential to dancing, have done far more to injure its repute among reasonable people than any fancied bacillus or morbid spore is likely to do.—*Lancet*.

THE ADVANCE IN LIFE-VALUES.

Dr. B. W. Richardson, in his abridgment of "The Health of Nations," by the late Sir Edwin Chadwick, under the heading "Progressive Health," compares the mortality in the Elizabethan and Victorian eras:

According to John Graunt's reports, from the parish registers, the condition of the whole city of London in the time of Queen Elizabeth was very much that of a "slum." The death-rate was in fact that of a slum, it was more than 40 per 1,000; but now, under some advance toward unity and centralization, it is about 20 per 1,000, still including upward of one-third of preventable deaths. The death-rate then largely exceeded the birth-rate, while now the reverse is the case. The death-rate of the children under 5 years was then one-third, or 33 per 100. It is now 27 per 100, and grievously too heavy. The deaths from old age, or the age then called old, of 70, were 7 per cent.; they are now sadly too low, but even in the city proper they are 18 per cent. As to personal security, John Graunt boasted that not more than one in 2,000 was then murdered annually, which he ascribes to good local government. At the same rate now murders in the whole of the metropolis should amount to no less than 2,500 annually, whereas they actually amount to an average of no more than 12 for the whole 5,000,000—a population which approaches to that of the whole kingdom of England and Wales in the time of Elizabeth.

LISTER'S METHOD DISCARDED BY LISTER

"Who could have foreseen the short existence of the world-renowned system of Lister, which has been for years the ideal of modern surgeons? Who could have dreamed that the idol would be one day broken by him who had placed it on a pedestal of bronze and polished brass?" Such are the questions with which the *Journal d'Hygiène* begins the announcement of the present status of Listerism, and goes on to remark: "It is, however, an historical fact. The dictum of Lister and his antiseptic doctrine have ceased to exist. In his remarkable communication to the Congress at Berlin, on the actual condition of the antiseptic treatment of wounds, the eminent English surgeon has given the following judgment:

"As regards the spray, I feel ashamed that I should have ever recommended it for the purpose of destroying the microbes of the air. If we watch the formation of the spray, and observe how its narrow initial cone expands as it advances, with fresh portions of air continually drawn into its vortex, we see that many of the microbes in it, having only just come under its influence, cannot possibly have been deprived of their vitality. Yet there was a time when I assumed that such was the case, and trusting the spray implicitly, as an atmosphere free from living organisms, omitted various precautions which I had before supposed to be essential."

Lawson Tait, of Birmingham, Bantock, of London,

and Bergmann, of Berlin, in reviewing their vast experience, are not afraid to affirm that antiseptic treatment must now yield the place to the aseptic method!

Water boiled or sterilized, a brush and soap are the simple means which have enabled these eminent surgeons to perform a series of one hundred ovariectomies without a single death.—*Cincinnati Med. News*.

THE VALUE OF TIME.

A correspondent, writing from a large commercial city, informs us that he remembers seeing many years ago the following in some mercantile offices: "Call upon a business man at business time only, and on business. Transact your business and go about your business, in order to give him time to finish his business." Our correspondent feelingly asks whether a notice similar to the above, with the necessary modifications, might not be hung up in the consulting-room and surgery of every busy consultant or general practitioner. Much has been said as to the rapidity with which the out-patients of hospitals are disposed of. But this rapidity is perfectly compatible with correctness of diagnosis, prognosis, and prescribing by an experienced practitioner, and there is something to be said on the other side—the time wasted by patients in prolix descriptions and tedious repetitions. The quaint story of the lady who consulted Abernethy and, knowing his impatience of such verbosity, held out her wounded finger and answered in monosyllables, is well known, and the example might be followed with great advantage. The lady in question was rewarded by Abernethy's impromptu praise, that she was the most rational woman he had ever met in his life. Those patients who are most considerate for their doctor's time are certainly the most welcome.—*Lancet*.

THE TIME OF DAY FOR OPERATIONS.

There is considerable difference of opinion amongst surgeons, as to whether it is best to operate early in the morning or in the afternoon. Many prefer the morning. They say that the patient is saved the suspense of being kept waiting till the afternoon, and the surgeon has the better chance of a good supply of sunlight or of its equivalent in this country. Both these reasons have considerable force. Other surgeons maintain that early operating implies a sleepless previous night. The shades of evening, a greater promotor of sleep than blinds and screens, come on sooner when the operation is performed in the afternoon. This physical fact also implies greater chances of rest in another respect, for there is less fear of subsequent disturbance from noises inside or outside the house when the surgeon operates late. Long operations may seriously tax the surgeon's strength and nerve, and in this respect again the afternoon is better for operating than the morning. In private practice and wherever freedom from noise and plenty of warmth can be ensured, the morning is probably the best time, especially in summer. As far as light—a most important factor—is concerned, the time of day makes little difference at this time of the year in London, though the danger of a sudden darkening of the atmosphere is, perhaps, greatest in the afternoon.—*British Medical Journal*.

PRACTICAL NOTES.

CHRONIC CONSTIPATION.

At the meeting of the Berlin Medical Society, Herr Flatau introduced a new method of treating chronic constipation due to torpor of the colon. This consists in applying about three grams of boric acid. In those cases in which the lower edge of the rectum protrudes through the anus and when this remains visible after powerful contractions of the levator ani and sphincters, the quantity of boric acid mentioned is either to be dusted on or rubbed on the mucous membrane in sight. In cases in which the mucous membrane is not visible, it must be insufflated. It is important that the medical attendant should carry out the procedure himself, at any rate at the commencement. The patient should then keep quiet for a time. In from an hour to three hours, peristaltic action will be observed in the colon. He has never seen a failure from this method of treatment, nor had he seen a case where the patient got so accustomed to it that it ceased to be effective. On the contrary, if carried out systematically daily, permanent improvement in time takes place, and normal peristalsis is returned to. He had tried a number of other substances but none had the same useful effect.—*Medical Press*.

SYCOSIS.

R Iodoform, 4 parts; lanolin, 30 parts. Leache recommends the above to be applied every night, and to be washed off in the morning with hot water.

MALIC ACID LOZENGES AS AN ANTICATARRHAL REMEDY.

Malic acid lozenges have recently found considerable favor in England as a remedy for sore throat and bronchial cough. They are reported as efficient not only in excessive secretion of mucus and cough, but also in catarrhal conditions of the bowels and in hæmorrhoids.

THE TREATMENT OF BURNS.

Bardeleben treats burns after the following plan. The injured part is first thoroughly washed with carbolic acid solution from 2½ to 3 per cent., or with a solution of salicylic acid about 3 in 1,000. All the bullæ are then punctured and the serum allowed to escape, after which the whole part is thoroughly dusted with finely powdered nitrate of bismuth, and a thick layer of cotton wool applied. The latter is changed whenever it is impregnated with the discharges from the wound. If the burn is a very extensive one, the powdered bismuth may be set aside, and a bis-

mutb ointment used instead. The author affirms that with this dressing cicatrization proceeds rapidly, and there is less discomfort than when any other dressing is employed. Despite the large quantities of bismuth that have been applied no toxic symptoms have been noted in consequence of its use.—*Med. Press and Circular*.

A NEW DIURETIC.

Dr. Gram of Copenhagen, has lately introduced a new drug known as diuretin. It is made by combining theobromin in such a way as to make it exceedingly soluble, of rapid absorption, and very pleasant to take. It has been tested clinically in Strasburg; is found to act directly on the kidneys without any action on the heart or nervous system, such as we have in digitalis and caffeine.—*Diétiéle Gazette*.

TREATMENT OF SYCOSIS VULGARIS.

Dr. Rosenthal proposes a method of treating sycosis which presents three great advantages: the absence of pain, relatively rapid cure, and facility of application. The diseased parts must be carefully scraped every day; and morning and evening, and also three times during the day, the following pomade should be applied:

Tannic acid, 1 gram.
Milk of sulphur, 2 grams.
Vaseline, 20 grams.

The face of the patient remains uncovered during the day. At night, after friction, an emollient paste is applied: Wilson's zinc ointment, salicylic paste, or Hebra's diachylon ointment. With the latter pomade, if the dressing be carefully made, the formation of a sulphate of lead is not to be feared. The author has lately employed with success the following paste:

Tannic acid, 5 grams.
Milk of sulphur, 10 grams.
Oxide of zinc, 17.5 grams.
Starch, 17.5 grams.
Vaseline, 50 grams.

This is applied morning and evening, gauze being placed above the dressing. Epilation is rendered unnecessary by this treatment.—*Annales de Derm. et de Syph.*, No. 4, 1890.

MENSTRUAL COLIC.

Dr. J. C. Da Costa prescribed the following in a case of menstrual colic:

R. Chloroform, pur. .
Spir. camphore, ℥ss.
Æther nitrosi.
Æther comp., ℥ss.

Sig. f5ss-j in 5j of water, containing 5j of spirit, frum. ment, every half-hour for three doses.

SOCIETY PROCEEDINGS.

Gynecological Society of Chicago.

*Regular Meeting, Sept. 26, 1890.*THE PRESIDENT, JAMES H. ETHERIDGE, M.D.,
IN THE CHAIR.DR. HENRY BANGA read a paper on
ECTOPIC PREGNANCY, WITH REPORT OF TWO
CASES.

(See page 121.)

DR. C. T. PARKES: With all of you I have been very much interested in these cases presented by Dr. Banga. I certainly was in favor of the opinion that all cases of extra-uterine pregnancy should pass into the hands of the laparotomist for treatment; but in looking up the cases I have had under my charge, somewhat to my surprise I came across two which were not treated by operative procedure, and which recovered. I have had seven cases under my charge, which I think were all cases of ruptured extra-uterine pregnancy, with the exception of the last one, which went on the full term and three months beyond full term; she came under my care with a dead fetus and well-marked symptoms of septic poisoning. The first two cases came to me some years ago, and in looking over my notes of these cases I am confirmed in the supposition I had then, that they were cases of extra-uterine pregnancy. This supposition was mainly based upon the symptoms mentioned by Prof. Banga as indicative of that condition, namely: 1. Acute and severe pain in the pelvis; 2. The usual symptoms of great loss of blood; 3. A previous history of several or many years of sterility; 4. Interruption of previously regular menstruation; 5. Enlargement of the uterus; 6. The presence of a tumor circumscribed in character, to be determined on one side or the other of the uterus if examined before rupture. If after rupture, the discovery of a large mass, doughy and inelastic, in the pelvis and lower abdomen; 7. The presence of a bloody vaginal discharge.

With this array of symptoms it seems hardly possible that the condition can be mistaken, and yet in contradistinction to that we must bear in mind the testimony of a man who has perhaps seen the greatest number of these cases—Mr. Tait. He says he has never seen a case of extra-uterine pregnancy before rupture; that every case that has come to him—thirty-seven in all—has been a case of rupture. So I must object a little to the idea that it is an easy thing to recognize the presence of extra-uterine pregnancy. Thirty-seven cases occurring in the practice of one man would rather indicate that physicians, as a rule, are able to recognize the condition only in its history, or are not aware of the value of these symptoms in all cases. In the first two cases I referred to, one

presented all the symptoms that I have passed in review and which were previously mentioned by Professor Banga; but she was not operated upon, because as that time I do not think much operating was done for these cases. She was treated for what was supposed to be a hæmatocele, and she went on in great danger for days and weeks, until I finally aspirated through the abdominal wall and withdrew a large amount of bloody fluid. I aspirated three or four times and she finally got well. The second case presented all these symptoms, and I would now without hesitation advise operation, as a case of extra uterine pregnancy. In this case an opening was made through the vagina and the extravasated blood and remnants drawn away, and the patient recovered.

These are two cases of recovery in which laparotomy was not done. The cases out of the seven, presenting symptoms of ruptured tubal pregnancy, in which laparotomy was done followed by recovery, I have already presented to this Society. The sixth case was a lithopedion, which I removed through the posterior walls of the uterus, and reported the case and exhibited the specimen to this Society. The seventh and last case was that of a lady who went three months beyond full term with an extra-uterine pregnancy and was taken with septic symptoms. I operated upon her and removed the entire sac and contents together. This case again proved what Mr. Tait says is so necessary to believe in these cases as a rule—that they are always outside of the peritoneum—and which is proven also by the frozen section described so beautifully by Mr. Hart. All the organs inside the peritoneum are shoved to one side and the pregnancy is outside, hence the method of treatment of the latter period of extra-uterine pregnancy. The going to full term is a matter of grave consideration and should be well understood. The method spoken of by Dr. Banga has been the one usually adopted—that is, opening down into the sac, sewing it to the wound of the abdominal walls, removing the fetus, and then packing the cavity with antiseptic gauze. Most of these cases, previous to antiseptic days, died of septic peritonitis. Since antiseptic precautions have been adopted there has been a decided improvement in the death-rate.

The method of treating the placenta is an item of great importance in such cases—that is, whether it should be left or removed. Lately an article from the pen of Dr. Braun has appeared in the *German Archives of Gynecology*, in which he reports two cases. In the first he opened the sac, sewed it to the abdominal wall, removed the child, and then tried to ligate the vessels of the placenta inside the sac and remove the placenta. The patient died from loss of blood. In the second case he opened and sewed the sac to the abdominal walls, but ligated the vessels outside of the sac

by means of stitch ligation, and removed the placenta with no loss of blood. The patient recovered. I think where the pregnancy has gone to full term, it is not best to wait until there is loss of blood from separation of placenta and inability to control it, but to follow the suggestion of Dr. Braun and primarily ligate the vessels outside of the sac, as can be done by means of a needle and ligature, then remove the placenta and pack the cavity with gauze dressing. That seems the safest way.

This is an important subject, and I certainly think the doctor's first patient was very fortunate in many ways, especially in that she fell into such skilful and efficient hands, with gentlemen who were familiar with such cases and able to recognize them early; because I believe, as a rule, it is a condition not easy to recognize. And she was still more fortunate in that she had the confidence a patient should have in the attending physician, and consented to an early operation. One cannot help for a moment agreeing that it is better to do laparotomy before than after rupture.

DR. W. W. JAGGARD: I have listened to the reading of Dr. Banga's paper with great interest. I wish to restrict my remarks to early tubal pregnancy, before and after rupture. In the diagnosis of Dr. Banga's first case there were two signs of pregnancy present that I do not remember having heard the essayist mention. One was the blue discoloration of the anterior vaginal wall, which was more marked in this case than I am accustomed to see it, even in normal pregnancy. Chadwick, in a very excellent paper read before the American Gynecological Society several years ago, calls attention to the diagnostic significance of the blue discoloration of the anterior vaginal wall below the meatus urinarius. The second point was Hegar's sign—the softening and compressibility of the lower uterine segment; compressed between the hand on the abdomen and the finger in the vagina, the lower uterine segment felt as thin as cardboard. A few days since, in conversation with Dr. Gehring, of St. Louis, he narrated a case in which the lower uterine segment was so thin and compressible that five prominent physicians of St. Louis diagnosed the case to be one of tubal pregnancy; it turned out to be a case of normal pregnancy. What was supposed to be the uterus was merely the vaginal portion; the lump in the abdomen, the corpus uteri, was separated by a long isthmus, the compressible, lower uterine segment.

The only condition that closely resembles early tubal pregnancy, in my experience, is pregnancy in a retroflexed uterus. During the last summer I saw a case (which a member of this Society had examined very carefully bimanually), and found the vaginal portion of the cervix very much elongated, the lower uterine segment very thin and compressible, so much so that one would not notice it at

all unless attention was called to it—behind the vaginal portion, a tumor. The woman had pain; slight hemorrhage, bearing down, and a discharge of something that was mistaken for decidua. Under the genu-pectoral position for a week, the nature of the tumor was disclosed; it was a case of pregnancy in a retroflexed uterus. The woman is now in her eighth month and expects to be confined soon.

In justice to the gentleman who first examined, it must be said that careful examination under an anesthetic would have disclosed at once the nature of this retro-uterine tumor. He did not make a positive diagnosis, but begged for an examination under an anesthetic, which was declined; and the patient came under the observation of Dr. Webster, of Evanston, and myself. As a general rule, when the conditions for bimanual palpation are favorable—that is, when the abdominal walls are thin and relaxed, particularly when the patient can be anesthetized—I do not think there is much difficulty in the diagnosis of tubal pregnancy before rupture. Moreover, I think there are usually present symptoms enough to attract the woman's attention to her condition and lead her to apply to a physician before rupture takes place.

I wish to congratulate Dr. Banga on his diagnostic skill in this case. It is certainly the first case in Chicago operated upon at so early a date and before rupture of the sac.

As regards treatment of tubal pregnancy before rupture, I think the weight of evidence and of responsible opinion is in favor of laparotomy with extirpation of the sac. It is true that feticide by means of electricity is defended, more particularly in the Eastern United States. I do not think this practice can be upheld on rational grounds nor upon the results that have followed the use of this method. The one individual to whom honor is due for establishing laparotomy before rupture is J. Veit, of Berlin, who has operated successfully on some seven cases.

The universal proposition that laparotomy should be performed in every case of ruptured tubal pregnancy cannot be accepted at the present day. The natural history of tubal pregnancy shows that in the majority of cases recovery results; there are five favorable terminations to one unfavorable. In the first place, the tube may rupture into the broad ligament, and we have the formation of a hematoma, or a broad ligament pregnancy, both relatively favorable terminations for the time being. Sometimes the tube ruptures and the egg remains *in situ*, acting as a tampon—also a favorable termination. Then we have the tube rupturing, and the product of conception, and blood, forming a retro-uterine hematocoele—a relatively favorable termination not demanding a primary laparotomy. I think the essayist goes a little too far when he says all retro-uterine hæm-

atocoles are the results of tubal pregnancy. That view was advanced years ago by Dr. Gallard, but it has been sifted down to about 75 per cent. due to ruptured tubal pregnancy. Finally we have the tube ruptured, with free intraperitoneal hæmorrhage, the woman dying either of primary hæmorrhage or from secondary peritonitis. There is only one among all these terminations that is unfavorable, and I think, therefore, it is not right to say perform laparotomy in every case of ruptured tubal gestation. Perform laparotomy when there are signs of free intraperitoneal hæmorrhage, when there is evidence that peritonitis will likely ensue. It must be borne in mind that in case of rupture before the third month the ovum is sterile and all its surroundings are commonly sterile, and in some cases even of intraperitoneal hæmorrhage the blood and fetus will be dissolved.

DR. D. T. NELSON: The subject has been so freely discussed that it is hardly worth while for me to take the time to discuss it more, especially as I can hardly differ from the expressions already made. However, I will refer to one case which I saw five or six years ago. This case was just beyond term, or perhaps exactly at term—it was difficult to determine the exact date of pregnancy. But she had had a kind of false labor, thought herself in labor, sent for a physician, who found there was some difficulty in a normal delivery and suspected extra-uterine foetation. The following day I saw the patient in consultation; there could be no question but that the woman was pregnant, and no question that the fetus was outside the uterus. After making an examination I became satisfied that the fetus was alive, but so very feeble that it seemed to me there was no hope of saving the child by operation; and then I had the thought, as I have now, that it is not the best time to operate at full term unless you can save the fetus. In this case there seemed no hope of doing this, because there were only the slightest movements, while the day before they had been fairly strong, and the day before that well-marked and active. I advised against operation at that time, as I thought there would be more likelihood of saving the mother by waiting until the placental circulation had diminished very considerably, as I believe it does after the death of the fetus. What has become of the patient I am unable to say.

DR. FRANKLIN H. MARTIN: I should like to make a few remarks on the power of electricity to destroy the fetus in these cases. I think it is a little too radical to say that no other treatment than laparotomy should be used for the treatment of tubal pregnancy; I believe, with those who have spoken to-night, that laparotomy should be performed for this condition if the diagnosis is reasonably certain, and the consent to an operation of all parties concerned can be obtained. If the patient has the confidence in her physician

that the patient exhibited in this case, and the operation can be done, then perform laparotomy. There are cases, however, where laparotomy will not be tolerated. Thomas in the lead, we have pretty good authority for the substitution of electricity in these particular cases.

In connection with this subject I have made some experiments. They are not extensive nor conclusive, but certainly suggestive; they are in the direction of determining which current to choose, if we decide to use electricity in these cases. I believe that Thomas and others recommend the faradic current in preference to galvanism. It has always seemed to me that it is desirable to employ every precaution against rupturing the sac; if this be so, and the foeticidal effects of galvanism and faradism are the same—that is, if they are equally efficacious—I should say under those circumstances use galvanism; because, if employed with an absolute gradual rheostat so as to produce no break, it can be applied with the minimum abdominal muscular contraction or other muscular contractions which favor the rupture of the sac. The experiments that I made were for the purpose of determining the relative foeticidal value of the two currents. The experiments were conducted by the employment of incubating hens' eggs. A given number of fresh eggs, all obtained from as near the same source as possible, were placed in an incubator and placed under the charge of an expert chicken breeder. These eggs were divided previously into four divisions, and properly marked. At the end of one week after the eggs were set two portions of the eggs were operated upon by electricity; one portion by a very strong (as strong as could be tolerated by an unanæsthetized patient) faradic current passing for five minutes; the other portion by a 20-milliamperè current, electrode 4 sq. cm. in area, also passing for five minutes. The galvanic current was applied by means of a gradual rheostat in such a manner as to produce no make or break in the flow.

At the end of two weeks of the incubation the other two portions of the eggs were treated by electricity in the same manner, with the exception that the faradic current was made much stronger (such as would be tolerated only by an anæsthetized patient) and the galvanic current increased to 50 milliamperes.

When the eggs had passed the allotted time for hatching, about 80 per cent. of the first lot acted upon by the faradic current hatched, while not one of those treated by the galvanic current hatched. Of the second lot about 60 per cent. remained undestroyed, while not one of the chicks treated by galvanism succeeded in piercing its shell.

This proved to my mind quite conclusively, as far as chicks are concerned, that electricity in the form of galvanism is much more efficient than

faradization; in fact faradization had little effect upon the eggs. If this same ratio of value should exist in the power of electricity to destroy the human ovum, we have an additional scientific advantage in galvanism in being able to regulate our dose. One can cause to pass through a fetus, encased in its sac exactly the same dose and the same density that caused the destruction of the fetus in these eggs, and I have no doubt whatever that a fetus of three or four months' growth would be deprived of life as effectually as the chicks were at the end of two weeks of incubation.

DR. CHRISTIAN FENGER: Mr. Chairman, Gentlemen of the Society: I have heard the paper with a great deal of interest, and congratulate Dr. Banga on his very successful operations. The subject of ectopic gestation in general, particularly the later stages, is too large for discussion in one evening.

It is remarkable how of late years the number of reported operations for extra-uterine pregnancy has increased. Let us take the last three years, 1887, 1888, 1889. In 1887 there were about 50 operations recorded, in 1888 there were 70 operations, and in 1889 110.

Of the 70 cases reported in 1888, 15 were of tubal pregnancy in which the early operation was performed—that is, before rupture—with 3 deaths, a mortality of 20 per cent. In two of the fatal cases the sac was fastened in the abdominal wound. In the remaining 13 cases total extirpation of the tube with its contents was practiced; the operation was, as a rule, comparatively easy, and the results consequently better.

Sixteen cases were operated upon at the time of rupture, with 5 deaths, a mortality of 31 per cent. or much greater than the mortality when the operation was performed before rupture of the sac. We may here mention Lawson Tait's 28 cases with only 1 death, a mortality of only 3½ per cent. From the report of these cases, however, it cannot be seen whether the operation was performed at the time of, or some time after, rupture.

Ten cases were operated upon several weeks after rupture, and only 1 died, a mortality of 10 per cent. At this time the patient has recuperated to a certain extent. This, of course, does not mean that the operation should not be done at the time of rupture.

Then, again, come the 6 cases Dr. Jaggard has mentioned, where nothing was done and only 1 of which died. Dr. Parkes and Dr. Jaggard have mentioned that the contents of the sac in early tubal pregnancy are aseptic and will not cause peritonitis.

In 1889 there are on record 75 cases operated upon in the first half of pregnancy, of which 10 died, a mortality of 13 per cent. Twenty-eight of these were operated upon before the rupture of the sac, all of which recovered; 21 were operated

upon at the time of rupture, with 17 recoveries and 4 deaths, a mortality of 19 per cent.; 26 were operated upon some time after rupture, when the patient had recovered from its immediate effects, with 20 recoveries and 6 deaths, a mortality of 23 per cent.

The entire mortality for the first half of pregnancy in 1888 was 26 per cent., while in 1889 for the same class of cases it was 13 per cent. The rapid increase in the number of cases reported shows either that now an earlier diagnosis is more frequently made or that laparotomy is now more readily resorted to for peri-uterine tumor, whether a positive diagnosis of tubal pregnancy can be made or not. We also see that early operation in extra-uterine pregnancy has given better results each succeeding year.

The rest of the statistics belong to the later periods of pregnancy, and I shall not mention them in this connection, because it really does not come under the subject of the paper—"Early Tubal Pregnancy, its Symptoms and Treatment." My own experience is almost none. I have seen one case where the sac had ruptured and very severe hemorrhage had set in, but in which, under expectant treatment, the patient finally recovered.

In 1888, the statistics gathered by Harris, of Philadelphia, showed twenty-seven cases of laparotomy with living children. Of these, twenty-five mothers died, and of the twenty-five living children thirteen died within fifty hours. This frightful mortality led Litzman to give the advice, based upon a record of twenty-six cases with six deaths, not to operate until the child was dead and the placental circulation had ceased, so as to avoid placental hemorrhage.

Lawson Tait was the first to take up a strong position against the practice of sacrificing children. He has recorded three cases of operation with living children, in which he saved all the children and two mothers. He further argues against Harris as to the lack of vitality in the children of extra-uterine pregnancy, stating that the three children above mentioned were living and healthy, so much so that one of the children he saved by this operation is his adopted son and prospective successor.

The operations recorded for 1889 show a great improvement in the results of operations in the last half of pregnancy, inasmuch as thirty-five cases had only six deaths, or 17 per cent. Furthermore, the operations with living children for the last two years tend to bear out Harris in his assertion that the regard for the child must be a secondary one, inasmuch as in eleven operations—six in 1888, and five in 1889—only four living children were saved, and as four out of the eleven mothers died, a mortality of 36 per cent.

As to the fate of the mothers when operating after placental circulation has ceased, there were

reported, in 1888, eighteen cases with six deaths; in 1889, twenty-six cases with three deaths; in all, forty-four cases with nine deaths, or a mortality of about 20 per cent. Thus it is safer for the mother, as Litzman proposes, as against Lawson Tait, to wait until the child is dead and the placental circulation has ceased.

In this connection I will also say that five years ago I thought exactly as Dr. Nelson does, and I think so now, and in a case of extra-uterine pregnancy present low down in the vagina, waited until the fetus had died, and then waited six weeks longer until the placenta had ceased to pulsate, and then still two weeks more in order to be safe. I then removed the child, which was at full term, through the vagina. The case has been mentioned in this Society, as Dr. Holmes was kind enough to see the case at the time with a view of determining whether such a fetus was septic or aseptic.

I do not see that we have time to discuss the details of the value of these late operations in extra-uterine pregnancy, whether through the vaginal wall or through the vagina.

DR. C. W. EARLE: In the very brief remarks which I will make I desire more particularly to speak regarding the diagnosis of these cases. In the discussion up to this time it would seem that about the only thing to be done is to stop the growth of the fetus either by electricity or morphine, or remove the sac by laparotomy. The most important but difficult question, in my judgment, is to arrive at a correct diagnosis. Dr. Jaggard's remarks reminded me of a case to which I was called in consultation a few months ago. It was believed to be a case of extra-uterine pregnancy, and the gentleman who asked me to see the case with him thought an operation would be necessary. He based his diagnosis upon the points Dr. Jaggard made—that is, the thin condition of the wall found by digital examination; the wall that separated the finger from the fetus did not seem thicker than a sheet of paper, and yet after careful examination we both agreed that the fetus was inside the uterus, and the case went on to a safe delivery at full term. A few minutes before I started for this meeting I took Winckel's last work, translated by Edgar, and jotted down the symptoms upon which he based his diagnosis. While he considers that it is a difficult condition to diagnose, he believes, after an experience in thirteen cases, that he can usually arrive pretty closely at a correct conclusion. He bases his diagnosis upon these symptoms: First, the cessation of normal menstruation, previously normal; second, hyperæmia and secretion of the breasts; third, hyperæmia and lividity of the vulva (this symptom has been thoroughly discussed by Dr. Banga and Dr. Jaggard); fourth, strong pulsation of blood-vessels in the vault of the vagina; fifth, softening en-

largement, and displacement of the womb; sixth, a clearly defined and growing tumor; and lastly, a murmur or souffle above the symphysis, heard at rather an early period. He insists on frequent observations and examinations, so that he can determine the rapidity of the growth of the tumor. I think Dr. Jaggard's statement that all authorities, except Americans, believe in early laparotomy in these cases, is a little too positive. In Winckel's book he states decidedly that he believes there is a chance for, first, electricity; secondly, for a trial with morphine or some of the other poisons that will destroy the life of the child.

DR. BAYARD HOLMES: The mother is exposed in extra-uterine pregnancy to an immediate and to a remote danger. The immediate danger is fatal anæmia when rupture of a tube takes place, and the remote danger is sepsis in a limited hæmatoma or in a retained dead fetus. For the anæmia there seems to be an indication for transfusion which may prove valuable. In a study of the bacterial condition of dead extra-uterine fetuses which I presented to this Society, my attention was called to the great danger of sepsis. Hæmatomata in other parts of the body are ordinarily removed without any febrile disturbance, except that early and transient rise which has been attributed to "ferment intoxication." The case is very different in those pelvic hæmatomata which are due to extra-uterine fetation. Both the retained dead fetuses and the hæmatomata in this region become infected, in the great proportion of cases, within six months, and a large percentage of the remainder by the end of a year. This fact, I believe, is to be explained by the cause of extra-uterine fetation, which there is great reason to believe lies in an antecedent infective inflammation in the tubes or the endometrium.

In order that an extra-uterine pregnancy may take place, there must be some malformation or deformity in the sexual apparatus. It does not take place in the normal condition of the tubes and uterus. That it may be a malformation we can readily see, because the present condition of the human uterus is evolved from a very large and divided uterus which is exhibited in the fetus and the lower animals. We may expect an occasional reversion to the original type, and hence a risk of extra-uterine fetation. Such an arrest of development cannot often occur, because anatomists do not find these deformities frequently.

Most cases of extra-uterine pregnancy are preceded by a long term of sterility following an unhealthy puerperium, which in itself points to some deformity in the sexual apparatus arising from one cause or another. It is probable that most of these cases of deformity are due to a process of inflammation, and that inflammation is due to sepsis, and sepsis is due to infection; that

accounts for the presence, in close proximity to this extra-uterine fetus, of septic material, and it is the presence of that septic material which converts the hæmatoma into an abscess. Of course we must always consider the possibility of pressure atrophy between the heavy, dead fetus and the contents of the bowel (hard feces) opening a communication between the bowel and the fetus and producing infection in that way. That must be considered in these cases, but it cannot well be considered in cases of large accumulations of blood. We cannot consider the possibility of suppuration or any septic decomposition of a large mass of blood without infection: that is impossible. Infection is rare through the circulation, but it is not wholly unknown. Therefore I look upon the indication to be these two: The dangers from hæmorrhage and the dangers from sepsis. But the danger from sepsis is imminent on account of the probable etiology of extra-uterine fetation.

DR. E. W. SAWYER: I will add but one thought, which was brought to my mind by the remarks of Dr. Nelson—that is, that a sort of false labor sometimes appears at term. This reminded me of a case I attended in 1874, with Dr. Justice, of Denver, in a little village in the foothills of Colorado called Boulder. The woman had expected to be delivered two years before our visit, and was visited by a very intelligent attendant who described a series of phenomena nearly approaching normal labor, which extended through a period of nearly twenty-four hours; then everything subsided. She carried her size for about a year, when she grew smaller and became active again. She was the wife of the proprietor of the single hotel there, and we visited her for the purpose of performing laparotomy. The details of the operation shock me now as compared to the precautions taken to-day. We operated and removed a fetus which weighed 4½ lbs. Its tissue was converted into a sort of adipocere, so that in flexing the elbows the tissues cracked. The sac contained much pus, and the precautions against sepsis were not to any degree observed. The poor woman died at the end of about three days.

DR. H. W. BANGA, in closing the discussion, said: As to the diagnosis of these cases, Dr. Jaggard mentioned a case of retroverted uterus that was taken for extra-uterine pregnancy, and remarked that probably by using an anæsthetic the true condition of the case would have been revealed at once; so I would repeat that for a correct diagnosis it is absolutely necessary to use an anæsthetic, as I think we ought to do, and probably most of you do in doubt about the nature of any pelvic disorder. Dr. Jaggard took exception to my statement that laparotomy should be performed in all cases of rupture. I see I did not make my statement plain enough. I had in view

what was *termed* (or called) extra-uterine pregnancy, thus excluding beforehand the cases of hæmatocoele. Up to a few years ago hæmatocoele was not described as one of the outcomes of a case of tubal pregnancy, and, as far as its clinical aspect is concerned, it takes an entirely different run from free rupture into the abdominal cavity. Since I have listened to Dr. Holmes' remarks I am more than ever convinced that laparotomy is the thing to be done in the latter cases.

I should think it only proper to try in this manner to stop the hæmorrhage if the symptoms show that internal hæmorrhage is the prime danger, or to remove a septic fetus and wash out the peritoneal cavity if sepsis is the more prominent symptom. In relation to this question of doing laparotomy, we must always bear in mind that from year to year laparotomy, as such, becomes less dangerous; and we all know, too, that as each of us sees more of these cases, we also have more personal confidence in being able to control sepsis. I must say that I consider the dangers incident to the operation, as such, to be very small. I further refer Dr. Jaggard to what I said about the treatment of hæmatocoele. I did not recommend any immediate surgical interference in those cases. I said I would first wait for resorption, because I knew that resorption is the rule in a case of hæmatocoele; should it fail to occur I would try an operation. Dr. Parkes related a case that he cured by aspirating; I have had a similar one. Then, if the symptoms warranted it, I would open and evacuate, either through the abdomen or through the vagina. In my second case, the steady increase of the tumor, causing intense pain, and the displacement of the bladder away above the symphysis, so that the patient was entirely unable to pass water, were the direct indications for operating. In cases of hæmatocoele there is very little danger of the patient bleeding to death, because, no doubt, the beginning of the hæmorrhage occurs into the distended tube or between the folds of the broad ligament. During the first hours or days it is a hæmatoma, and only after the tension of the bloody tumor has become such that the covering peritoneum finally tears will there be a free effusion of blood into the abdominal cavity. This was quite plain, I think, in my second case. There was a hæmatocoele filling out the Douglas cul-de-sac up to near the umbilicus, and inside of this sac was what we might call a hæmatoma of the left broad ligament, or rather a hæmatomosalpinx, because the big coagulum corresponded to the middle of the left tube, both ends of which were torn by the accumulation of blood within.

Hardly ever is there any immediate danger from hæmorrhage in case of hæmatoma or hæmatocoele, because the coagulum which forms at the seat of the first oozing acts as a compressing tampon on the ruptured blood-vessels. But where the sac ruptures freely into the abdominal cavity,

the patient is liable to bleed to death, either in a few hours or a few days. I remember about nine years ago having seen such a case. It was a very hot day in July. The lady was getting ready to go down town, and while she was standing before the glass, giving the finishing touch to her toilet, she was suddenly seized with vertigo and a sharp pain in her abdomen; she began to vomit, and had all the symptoms of cholera morbus. Several physicians were sent for, and, as she had diarrhoea and tenesmus within an hour of the first attack, they took it for a case of cholera morbus. This occurred about 10 o'clock in the morning, and I was called in about 9:30 in the evening. At that time I was making reports from German periodicals for Dr. Mundé, and there was much discussion going on about extra-uterine pregnancy; so that when I saw the patient I at once thought, "I wonder if this is not a case of rupture of an extra-uterine ovum?" She was almost bloodless; the lips and conjunctiva had lost all color; she was breathing heavily, had no pulse; the skin looked waxy and was covered with a cold sweat; she was apparently dying. By digital examination I found the posterior cul-de-sac bulging down, giving a peculiar doughy, soft touch, which to me plainly demonstrated an accumulation of something like coagulated blood.¹ While I was there the patient died. I was so much interested to know what it was that I got permission of the husband to make a post-mortem. On opening the abdomen the black, half-coagulated blood welled out, and, after removing it, I found a tubal ovum about as large as a big plum, which had burst, thus causing unimpeded oozing of blood, and death. The patient had been married eight weeks; had gone two weeks over her last menstruation.

I should think it impossible to confound a case of free hæmorrhage into the abdominal cavity, and a case of hæmatoma or hæmatocele retro-uterina.

To Dr. Parkes I would say I did not leave any coagula in the hæmatocele sac; I opened it and scooped it out with my hand. Of course there is nothing so apt to undergo quick disintegration as blood.

FETUS PAPYRACEUS.

DR. W. W. JAGGARD: My friend and former pupil, Dr. A. E. Froom, of Chicago, gave me the specimen that I have the honor to present.

History.—May 1st, 1890, Dr. Froom was called to see Mrs. M., age 21 years, recently married; three months advanced her in first pregnancy; suffering from nausea and vomiting. The complaint not yielding at once to the usual simple remedies prescribed, the patient applied, but without bene-

fit, to several prominent physicians. Finally, about the fifth month, she returned to Dr. Froom. At this time the woman was in a most distressing condition—incessant vomiting and retching, diarrhoea, bloody stools, tormina and tenesmus, fainting spells. The woman complained of intense vulva and anal pruritus, and upon examination Dr. Froom discovered a "scaly eruption about the parts," and infiltration of the inguinal glands on both sides. Alopecia was also observed. The diagnosis of syphilis was made, although a careful search failed to reveal the initial lesion.

Under the exhibition of mercury the woman showed immediate and marked improvement.

August 12th patient fell in premature labor. Patient had not been able to perceive fetal movement for the week previous, and the heart tones were not perceptible. After four hours of labor a macerated foetus, corresponding to the seventh month, was expelled; it was followed in ten minutes by the placenta. Dr. Froom was about to irrigate the uterine cavity when he noticed the intact membranes of a second ovum presenting at the os externum. This second ovum, corresponding to the third month, was easily expressed. Puerperium normal; uterus is single. The father admits syphilitic infection three years ago.

The specimen consists, as you see, of a twin pregnancy.

The first twin, female, length 35 cm., weight 1172 gm., with its macerated epidermis, is a typical example of the *fetus sanguinolentus* (E. Martin). It corresponds to the seventh month. It also presents certain objective signs of syphilis that are perfectly distinct from mere cadaveric changes. These are: 1. The line of syphilitic osteo-chondritis at the junction of the diaphysis with the epiphysis in the long bones, described by Wegner. In this specimen you can see this line in the upper and lower epiphyses of the femur. 2. The spleen is greatly increased in volume, consistence, and weight. It weighs 12 gm., or 0.98 per cent. of the total weight of the fetus, while the average normal weight of the spleen at birth is 9 gm., or 0.3 per cent. of the body weight. According to Ruge, in normal fetu, under 2,000 gm. the weight of the spleen is $\frac{1}{100}$ of the body weight; in non-syphilitic macerated fetu, $\frac{1}{100}$; in syphilitic macerated fetu, $\frac{1}{100}$. In this case the spleen is $\frac{1}{80}$ of the body weight. 3. The liver weighs 52.5 gm. According to Ruge, in normal fetu under 2,000 gm. the weight of the liver is $\frac{1}{100}$ of the body weight; in non-syphilitic macerated fetu, $\frac{1}{100}$; in macerated syphilitic fetu, $\frac{1}{100}$. In this case the liver is about $\frac{1}{80}$ of the body weight.

No gross lesions were detected in the cord, lungs, liver, spleen, and these organs have not yet been examined microscopically.

Unfortunately, the placenta was thrown out by the nurse. Dr. Froom said the cord was cedematous (?), and that an amber-colored, transparent

¹ As it is I have read since claims that it is impossible to diagnose by digital examination an accumulation of coagulated blood in the abdominal cavity.

substance, of the consistence of jelly, was attached to the membrane.

The ovum of the second twin is intact; its weight is 88.5 gm., and it presents an instance of mummification—the usual post-mortem change in feti between the third and sixth months *in utero*. The placenta, fully formed, is flattened and compressed into a solid disc 10 cm. in diameter. The liquor amnii has disappeared. The foetus, about three months old, male, 13 cm. in length, is a typical example of the *fetus papyraceus*—the form commonly observed when a dead foetus, retained *in utero* for a considerable period, is strongly compressed and flattened out, as the name implies. The conditions for this peculiar mode of compression are best supplied in twin pregnancy, in which, while one foetus dies, the twin goes on to complete development.

The points of interest in this specimen that I beg to mention are:

1. These feti—each with its own placenta, chorion and amnion; the one female, the other male—contained within the same single uterine cavity, are probably the resultants of the simultaneous fecundation of two ova. These ova may have come from the same Graafian follicle, or from the same ovary, or from both ovaries. According to the old view, the fact that the placentae are entirely separate would indicate that the ova did not come from the same ovary. For some cause, not now discoverable, the ovum containing the male was crowded to the wall by the other, and converted into this flattened-out, paper-like mass.

The specimen, probably, is not an example of superimpregnation. While the possibility of superfecundation—that is, the successive fecundation of two or more ova out of the same ovulation period—in the human animal must be admitted, its actual occurrence has never been demonstrated. The not uncommon occurrence, 1, of a white woman having twins, one a mulatto, the other white; and 2, of a black woman's twins, one black, the other a mulatto, does not prove successive fertilization by different men. Kussmaul has correctly pointed out that in the crossing of races the offspring may resemble most closely either parent, so that a white infant born of a white woman may be the legitimate child of a negro. Schultze emphasizes this opinion, and demands, for the demonstration of superfecundation, two different children of a white woman after cohabitation with two men differing in race from each other and from the mother. Such an observation up to the present has not been recorded. Undoubtedly superfecundation occurs in mares, bitches and cats, among the lower animals, but then multiple pregnancy is the normal among these animals, while it is exceptional and closely allied to the abnormal in the human animal. Conclusions drawn from observation of the lower animals accordingly cannot be applied directly to human beings.

The principal arguments against *superfecundation*—that is, conception during pregnancy, lie in the suppression of ovulation and the disappearance of the cilia of the epithelium of the endometrium during gestation, and finally the entire absence of observations, that would make this hypothesis plausible.

2. First pregnancies are seldom multiple pregnancies.

3. The objective signs of syphilis in the macerated foetus, that are perfectly distinct from the cadaveric changes of non-syphilitic macerated feti retained within the cavity uteri. I venture to emphasize this point, because it is a common error to regard all macerated feti as syphilitic. Indeed, between 70 and 80 per cent. of such cases are syphilitic, but there remains a certain number in which the *fetus sanguinolentus* is merely the result of cadaveric change. In some of these cases of the latter class, it is very difficult to make an anatomical diagnosis, since the relative increase in the weight of the viscera is not an absolutely certain sign of syphilis, and the normal line of Guérin may come to resemble the osteo-chondritis described by Wegner.

EXHIBITION OF BROMIFORM.

DR. CHAS. W. EARLE: I want to occupy two or three minutes of the time of the Society in the consideration of a very unpopular procedure—that is, the administration of medicine—and introduce to your notice bromiform, the latest remedy for whooping cough. About six weeks ago my attention was called to this drug by an article in a German paper, and about that time an article was also published in the *Medical Record* by Dr. Fischer, reporting some sixteen cases to which he had administered it with marked benefit. By this time I had procured the medicine, and have now had experience with it in six cases. In five cases there has been marked improvement, although it was not a fair trial, because they had passed pretty well along into the second stage and had commenced to recover. In some of these cases there were thirty paroxysms a day previous to administering the drug, and in four days the paroxysms had been reduced to ten. It has rather a sharp, pungent odor, and it is best administered in syrup of acacia. I usually combine it with a little paregoric. The dose for a child two years of age is two drops, a child four years old four or five drops. Usually the administration from twenty to sixty drops in five or six days lessens the number of paroxysms. It is best given after meals; and the children to whom I have administered it have made no objection to taking it. It is recommended by several of the leading practitioners in Vienna, and I bring it before the Society because we are having considerable whooping cough and I think it would be well to give it a trial.

SPECIAL CORRESPONDENCE.

Treatment of Blepharospasm.

To the Editor:—In the last number of THE JOURNAL (December 27, 1890), under the heading of "Treatment of Blepharospasm," Giraud, (*Thèse de Paris*) is quoted as treating this annoying and at times intractable affection by forcible dilatation, using a pair of retractors or a spring speculum—the separation of the lids being carried to a degree of exposing the conjunctival cul-de-sac—and keeping the eyelids in this position for three or four minutes. For several years I have been using a similar method in my clinic at the New York Eye and Ear Infirmary—with the difference that I do not forcibly put the orbicularis palpebrarum on the stretch. The good results, not from stretching, but from the exposure of the sensitive cornea to daylight—the natural stimulus of the eye. In all cases of conjunctival or corneal trouble this procedure cures the blepharospasm if it exists. The speculum is put between the eyelids and opened so as to expose the cornea. Patient is kept with the eye exposed to diffuse daylight from five to ten minutes. I find that most of the cases occur in children and are due to phlyctenular keratitis. In many of the cases the photophobia is very great, and the children avoid light with might and main. The little sufferer buries its face in the pillow or the mother's breast. With this condition existing for a few weeks—the room darkened, perhaps—it is easy enough to imagine how a blepharospasm comes on. If the child is placed in an upright position or put on its back, the chances are that it will begin to sneeze. This is due to the change in temperature that takes place in the nose. When the head is buried in the breast or pillow the nose is kept unduly warm by the breath, but on changing from the bent position, so that the breath does not unduly heat the nose, the sneezing begins, the slight change in temperature is sufficient. In this connection I may add that it is not the light which causes the child to sneeze, as some suppose.

With regard to the suggestion of using an eye speculum in blepharospasm, the credit, if I am not mistaken, belongs to the late Dr. C. R. Agnew. Very truly,

PETER A. CALLAN, M.D.

New York, December 29, 1890.

Shall The Journal be Removed to Washington?

To the Editor:—I cannot see any valid reason for changing the locality of publication of THE JOURNAL. If at any time it could be shown that the interest of THE JOURNAL and of the members of the Association would be enhanced, then I am

ready to coöperate with the members in such action. It seems to me removal to Louisville, Cincinnati or New York would be just as good as Washington. Facilities of mail are such that subscribers will receive THE JOURNAL within a few hours as soon from Chicago as any other point.

N. HOLTON, M.D.
Harkers Corners, Ill., Jan. 13, 1891.

To the Editor:—By all means *do not* remove THE JOURNAL office. Chicago I consider by odds the *very best* place for the office for several splendid reasons; the first I consider enough—"that it is so easy of access from any part of the United States." I also think that there are a good many other *good* reasons in favor of Chicago, but do think this one enough, especially when compared with Washington, which place I think has no *good* reason in favor of such a removal.

H. K. TEFFT, M.D.
Topeka, Kan., Jan. 11, 1891.

To the Editor:—I am opposed to the proposition made to move the publication office and management of THE JOURNAL of the Association to Washington City. I vote CHICAGO to be continued as its permanent home because it is most central and has unexcelled mail facilities to all parts of the country, and because it is now and will continue to be nearer the centre of population, and destined to be the greatest medical centre of the United States.

I would formulate a ballot and distribute to every member of the Association, requesting his vote on location, with signature and P. O. address, to be returned to the committee having the question of location in charge. This seems to be the legitimate way to satisfactorily settle the issue.

W. W. HESTER, M.D.
3640 Cottage Grove Ave., Chicago, Jan. 16, 1891.

To the Editor:—While there appear so many reasons for keeping THE JOURNAL where it is, I oppose the question of removal. It would seem that the facility of distribution which the present location affords should decide the matter if nothing else does.

I second Dr. Dimmitt's motion that a vote be taken at an early date. This will give every member a chance to express his opinion.

W. E. WARD, M.D.
255 North ave., Chicago, Ill., Jan. 17, 1891.

To the Editor:—I am opposed to moving THE JOURNAL to Washington or any other city. The suggestion of Dr. Dimmitt's (January 17) is a good one.

J. N. DIXON, M.D.
Springfield, Ill., Jan. 19, 1891.

To the Editor:—There is no city in the United

States more suitable for the publication of THE JOURNAL than Chicago. It is unwise to move, and it is the height of folly to move THE JOURNAL from a large, rapidly growing city with its large material for journalism, to a small town, even though it be the capital of the country.

J. F. JENKINS, M.D.

Tecumseh, Mich., Jan. 19, 1891.

To the Editor:—Let THE JOURNAL remain where it is.

I. N. BRAINERD, M.D.

Alma, Mich., January 19, 1891.

To the Editor:—From a common-sense view of the subject, it does appear that a petty rivalry plays a prominent part in the controversy.

If there is one cause more patent than all others why THE JOURNAL should be moved, it perhaps lies in this query: Is it more profitable to cater to the whims of one faction rather than observe the old adage, "let well enough alone?"

Whilst it is probable that THE JOURNAL would receive an additional support, both in contributors and readers, if moved, yet this gain would most likely be at the expense of losing some of the present support.

But for a solution of this problem, much of course depends on a proper appreciation of the rivalry existing between the two sections, and the bearing of this rivalry on the medical profession.

A medical journal in any section of the country, receives most of the support from the near surroundings, and becomes identified with the writers of that section. A journal in the East is supported mainly by Eastern writers, in the West by Western, and in the South by Southern writers. This is all well enough generally, but when a journal belongs to a National Association, such a tendency to become identified with any one section, to the exclusion of all others, is detrimental to the better interests of the Association, and should be thwarted in its incipency.

To argue that THE JOURNAL, if moved to the East, would not, in after years, become identified with Eastern writers to a very great extent, seems contrary to our past observation.

Chicago is neither Eastern, Southern, nor extremely Western, and should be taken as a liberal compromise.

To let it remain would only disappoint a small number of the Eastern members of the Association, but to remove it to Washington would meet with almost the unanimous opposition of the North, South and West. The postal facilities are such that it makes but little difference whether THE JOURNAL is printed in Maine or California.

Should it be removed to Washington, the Eastern correspondents would have to send their communications and receive their JOURNAL by mail, just the same as at present. It is no more trouble

nor expense to address THE JOURNAL at Chicago than at Washington. Then what is to be gained by removing it to Washington?

W. F. ROCHELLE, M.D.

Jackson, Tenn., January 19, 1891.

NECROLOGY.

DR. ARCHIBALD O. AMEDEN, formerly of Ticonderoga and health officer of Glens Falls, N. Y., died suddenly in his office, November 28, of cardiac disease. He graduated from the Medical Department of the University of Vermont in 1865, and was a member of the Warren County Medical Society.

DR. GLOVER PERIN, Colonel and Assistant Surgeon General, U. S. A., retired, died at his home in St. Paul, Minn., December 15. He was appointed Assistant Surgeon U. S. A., from Ohio, December 4, 1847, and attained the rank of Surgeon and Major May 21, 1861. His experience covered the Mexican and Civil Wars. He was Medical Director of the Department of the Cumberland, headquarters at Louisville, Ky., during the latter contest, in which capacity he displayed great administrative ability, and later he was in charge of one of the general hospitals in Evansville, Ind. After the close of the war he served as Medical Director of the Department of the Missouri for six years, and the Department of the Dakota from 1883 to his retirement in 1887.

DR. FREDERICK SALZER, one of the Professors of Surgery at the University of Vienna, died somewhat unexpectedly on Nov. 30. He had been just twenty years in the professorate. The *Brit. Med. Journal* says: "In him consummate surgical skill was associated with remarkable good luck in respect of the results that followed his operations, two things that do not always go together. He did not wield the pen with the same facility as he used the knife, and he contributed comparatively little to surgical literature." He was sixty-three years of age.

DR. ALFRED F. HOLT died in Martin, Fla., whither he had gone in quest of health, Dec. 28, 1890. He was graduated from the Medical Department of the University of Vermont in 1860, and joined the 30th Massachusetts Infantry a year afterward, as Asst. Surgeon, but was promoted Nov. 26, 1862, to be Surgeon of the 1st Texas cavalry, and was mustered out as the Lieut.-Colonel commanding of the latter regiment May 20, 1865. He performed many acts of personal heroism in carrying wounded soldiers off the field of battle, and was commended in general orders for his bravery. At the time of his

death he was Surgeon-General of the Massachusetts Volunteer Militia, having been appointed by Gov. Robinson Jan. 3, 1884, and also U. S. Pension Examiner for Cambridge, Mass.

MISCELLANY.

LIST OF PERMANENT MEMBERS.—The following names were omitted from the List of Permanent Members: Dr. M. H. Burton, Troy, N. Y.; Dr. J. R. Hinkle, Sullivan, Ind.; and Dr. S. J. Wright, Tallmadge, O.

HEALTH IN MICHIGAN.—For the month of December, 1890, compared with the preceding month, the reports indicate that puerperal fever, cholera infantum, pleuritis, membranous croup, pneumonia, inflammation of bowels, inflammation of brain, measles and whooping-cough increased, and that typhoid fever and scarlet fever decreased in prevalence.

Compared with the preceding month the temperature was lower, the absolute humidity was less, the relative humidity was slightly more, the day ozone and the night ozone were more.

Compared with the average for the month of December in the four years 1886-1889, pleuritis, membranous croup, influenza, puerperal fever, cholera infantum, bronchitis and cholera morbus, were more prevalent, and measles, typho-malarial fever, whooping-cough, and typhoid fever were less prevalent in December, 1890.

For the month of December, 1890, compared with the average of corresponding months in the four years 1886-1889, the temperature was slightly lower, the absolute humidity and the relative humidity were slightly less, the day ozone was slightly less and the night ozone was more.

Including reports by regular observers and others, diphtheria was reported present in Michigan, in the month of December, 1890, at 70 places, scarlet fever at 100 places, typhoid fever at 41 places, and measles at 33 places.

Reports from all sources show diphtheria reported at 5 places more, scarlet fever at 32 places more, typhoid fever at 6 places less, and measles at 10 places more in the month of December, 1890, than in the preceding month.

LETTERS RECEIVED.

Dr. F. W. Samuel, Louisville, Ky.; Dr. M. W. Scott, Emerado, N. Dak.; Canton Surgical & Dental Chair Co., Canton, O.; Dr. J. J. Winn, Norwood, O.; Dr. W. E. B. Davis, Birmingham, Ala.; Dr. B. W. Davis, Montgomery, Ala.; Dr. E. B. Woodruff, Auburn, N. Y.; Dr. E. P. Robinson, Orange City, Fla.; Valentine's Meat Juice Works, Richmond, Va.; Dr. M. A. Bogie, Kansas City, Mo.; Dr. W. H. Siebert, Steelton, Pa.; Miss Mary D. Troye, South Manchester, Conn.; Dr. A. O. Gilman, St. Cloud, Minn.; Worcester District Med. Association, Worcester, Mass.; Dr. L. G. North, Tecumseh, Mich.; Dr. E. H. Dudley, Janesville, Wis.; Dr. G. W. Murphy, Danbury, Ia.; Drs. J. W. and R. La Grange, Marion, Ia.; Dr. John Casson, Alexandria, La.; Dr. R. J. Cook, Dr. A. L. Hammel, G. H. Rigby, Philadelphia; New Table Co., St. Louis, Mich.

Official List of Changes in the Stations and Duties of Officers Serving in the Medical Department, U. S. Army, from January 10, 1891, to January 16, 1891.

First Lieut. Henry D. Snyder, Asst. Surgeon, is relieved from duty at Ft. Reno, Oklahoma Ter., and will report in person to the commanding officer, Camp Guthrie, Oklahoma Ter., for duty at that station, relieving Capt. John L. Phillips, Asst. Surgeon. Capt. Phillips, on being so relieved, will report in person to the commanding officer, Ft. Reno, Oklahoma Ter., for duty at that station. By direction of the Secretary of War. Par. 16, S. O. 14, A. G. O., Washington, January 14, 1891.

PROMOTIONS.

To be Asst. Surgeon with the rank of Captain, after five years' service, in accordance with the Act of June 23, 1874:

Asst. Surgeon Henry S. T. Harris, January 5, 1891.
Asst. Surgeon Leonard Wood, January 5, 1891. A. G. O., Washington, January 12, 1891.

Official List of Changes in the Medical Corps of the U. S. Navy for the two Weeks Ending January 17, 1891.

Surgeon M. L. Ruth, ordered to the U. S. S. "Newark," February 2, 1891.

P. A. Surgeon W. H. Rush, detached from U. S. S. "Saratoga," and to the U. S. S. "Newark," February 2, 1891.

P. A. Surgeon Richard Ashbridge, ordered to the U. S. S. "Saratoga."

Medical Director W. T. Hord, ordered as President of Medical Board, to relieve Medical Director J. Y. Taylor.

Medical Director R. C. Dean, detached from hospital, Chelsea, and to Medical Board, Washington.

Medical Director J. Y. Taylor, to be placed on the Retired List January 22.

P. A. Surgeon W. H. Rush's orders to the "Newark" are revoked.

P. A. Surgeon Richard Ashbridge's orders to the "Saratoga" revoked, and orders.

P. A. Surgeon A. G. Cabell, detached from ironclads and to the "Newark."

P. A. Surgeon G. P. Lumsden, ordered to the ironclads at Richmond, Va.

CORRIGENDA.

In the List of Permanent Members published in THE JOURNAL for Dec. 27, 1890, page 937, for Wm. J. Crow, read McCarey, page 937, the address of Dr. Richard Robinson should read *Danville, Conn.* that of Dr. W. J. Robinson, Lupe, *Mich.*, and that of Dr. E. Paul, *Memphis, Tenn.*

ADDRESSES.

THE PHYSICIAN AS A MAN AND A
CITIZEN.

*The Presidential Address delivered before the Medical Society of the
District of Columbia on December 17th, 1890.*

BY SWAN M. BURNETT, M.D., Ph.D.,

PROFESSOR OF OPHTHALMOLOGY AND OTOLGY IN GEORGETOWN
UNIVERSITY, OPHTHALMIC AND AURAL SURGEON TO THE GAR-
FIELD, THE PROVIDENCE, AND THE CHILDREN'S HOSPITALS.
DIRECTOR OF THE EYE AND EAR CLINIC AT THE EMER-
GENCY HOSPITAL AND CENTRAL DISPENSARY,
WASHINGTON

Fellow Physicians: The revival of an old cus-
tom of the Medical Society of the District of Col-
umbia has imposed upon me, as its retiring Presi-
dent, the responsibility of this occasion.

Though feeling keenly my inability to do full
justice to the opportunity, I am yet glad, in so
far as it allows me thus publicly, at the close of
our year's labor together, to express my personal
thanks to you for the efficient manner in
which you have seconded all my endeavors, as your
presiding officer, in furthering the work of the
Society, and to congratulate you upon the char-
acter and amount of the work accomplished.

The work of the year 1890 has equalled, if not
surpassed, in importance, in both these particu-
lars, that of any preceding year in the history of
the Society. The papers have been large in num-
ber and varied in their subject matter, and have
been discussed, as a rule, freely, but always in
the friendliest spirit of purely scientific interest.
For all this I am happy to take this opportunity
of placing the credit where it justly belongs,
namely, to the untiring energy of the Committee
on Essays,—and particularly its most efficient
Chairman, and to the ready and generous re-
sponse the members have given to the calls made
on them for essays and discussions.

I desire also to express again my profound ap-
preciation of the honor you conferred upon me in
electing me to preside over your deliberations for
one year. It was an expression of confidence
which, I assure you, I shall always retain among
the pleasantest memories of my professional ca-
reer. I have received at your hands, nothing
but the most respectful consideration and kind-
ness; and the problem of this evening's perform-
ance, in which I am expected to discharge in a

measure this obligation, has, I must confess,
weighed not a little upon me. I carried it with
me on my summer's vacation beyond the sea and
revolved it oft-times in my mind as I speeded
along between ocean and sky, trying to find the
theme most fitting to the occasion. Not that
there are not plenty, and to spare, of problems in
medicine, which are awaiting discussion and so-
lution at our hands, but for ten months in the
year we are struggling with these scientific ques-
tions and fighting inch by inch toward the goal of
truth in the diagnosis, etiology, pathology and
therapeutics of disease. It is but nature, there-
fore, that you should, for the nonce, become
somewhat weary of these, and desire a change in
the trend of thought.

We are physicians and we love our noble call-
ing but the questions must often come to us, Are
we physicians and nothing more? Are we mere
diagnosticating and healing machines, grinding
out opinions and advice as the grist comes from
the mill? Is our outlook upon the world only on
perverted function and diseased and disordered
action? Is humanity only one vast museum of
pathological specimens for our contemplation and
study? And the thought came to me as it has
often come before, that neither we ourselves, nor
the world at large, are wont to regard sufficiently
the importance and the needs of the man back of
the physician. And as I saw and mingled more
with that immense congregation of medical men
which convened at the German capital, and was
able to study them collectively both at work and
at recreation, the more was impressed upon me
the necessity of calling a halt and taking stock of
ourselves, as it were, and considering whether or
not we are in danger of allowing the profession to
dwarf many of the essentials of our true manhood.

I have therefore thought it might redound to
our advantage if, for this one night in the year,
we laid aside the consideration of technical ques-
tions and, under the bond of our association, re-
garded ourselves in the light of men and citizens,—
coequal with men in other callings and other citi-
zens interested in the common weal of the State.

This proposition would seem so self-evident as
to require only its simple statement to find a gen-
eral acceptance of its truth and necessity; and
theoretically it probably is accepted by a large

part of the thinking members of our profession who have reflected on the matter at all, but only, I fear, in a general and very indefinite way; and besides, there comes, from time to time, from some of the wisecracks of the profession, a counsel to the younger men and a warning to the older men, to beware of being anything besides doctors. The community, it is said, looks with suspicion on the physician who feels and manifests an interest in anything outside of his calling, to attend, physically, to the sick; that our great and noble art is a jealous mistress and will tolerate no rival in her love and devotion. All of which is regarded as very fine sentiment, no doubt, by those who promulgate it; and, it must be confessed, that the manner in which the practice of medicine is sometimes tacked on to some other vocation like the tail to a kite, is calculated, and very properly and justly, to bring discredit upon the one who thus far fails to recognize the duties of life, either as regards himself or the community in which he lives. Of him and to him we have nothing to say. Being joined to his idol we, wisely, let him alone. But to the army of earnest workers in our profession, who have by their labors and self-sacrificing devotion brought it to the high level which it at present occupies, there is something to be said on the other side, which I believe will lead to their own personal advantage, and that of the profession in general and to the lasting benefit of the State.

Man is distinctively a social creature. In that fact lies his preëminence among created beings, because in that he has the power which no other of the animal creation can use to the same extent, of each working for all and all for each. And not only that, but, under a proper organization of society, it is permitted of one generation to reap and enjoy the fruits of the labors of the generations that have preceded it, and of planting for the harvest of its successors.

So important is this organization for the welfare not only of society itself, but of every individual member of it, that it has come to be recognized as a fundamental law in sociology that a man's first duty is to the State, his second to his family and his last to himself. Now, we are each of us, first, and above all other things, members of this organized society which we call the State, or government, and we are men and citizens before we are doctors, or lawyers, or preachers, or merchants, or laborers in any special field of activity, and our first duty is for the preservation of that organization and its advancement in that direction which shall secure to each member thereof those rights, privileges and opportunities, which shall lead to the greatest good to himself and the community at large. Even from the most selfish standpoint this cannot but seem reasonable and its truth must appear axiomatic in its simplicity.

This, then, being true, even if we have performed our duties faithfully as physicians, we may have yet failed in the first requisite of good citizenship if we have neglected to let our voice be heard in the management of affairs. I am well aware that in this opinion I shall be opposed by a certain and quite numerous class both in the profession and out of it, who hold that so long as a man has fulfilled his professional or business obligations he can, with a clear conscience, fold his hands and thank God that he is not mixed up with the turmoil of politics or public affairs of any kind, and that it is derogatory to the dignity of the profession to allow extraneous matters of a public character to obtrude themselves upon the time and attention of the physician who has already as great a load of responsibility as he can be expected to carry. A moment's reflection will show that this is a very narrow conception of man's duties, and a view of life's responsibilities from a very low plain. Because a man is a physician he is not thereby absolved from his duty as a citizen any more than are those in other callings. There are, of course, certain of these general duties which come in direct conflict with the proper performance of his purely professional activities, but outside of these there is no reason why a physician should hold himself aloof from the affairs which concern the community at large of which he forms a part.

It will be instantly said by some: "You would not have a doctor dabble in politics, contaminate himself with party squabbles and lower himself into the sloughs of party chicanery and corruption?" He who asks such a question can have no proper conception of his duties as a citizen. If all men who follow callings which are classed as respectable, and all men belonging to the learned professions and the cultured class kept themselves away from affairs of State and took no interest in the workings of the government, then indeed would the advance of civilization be in peril. But no man need lower or bemean himself by assuming his proper position as a member of the State organization. The discharge of no duty can be degrading, and if politics in this country have become a byword of reproach and a synonym for dishonesty and intrigue, it is because decent, intelligent, and well-informed men have failed to take their part in the proper organization and conduct of the parties representing the different views on matters pertaining to legislation. Of course it is not to be supposed that every doctor should turn active politician, but it should be expected that every citizen who has the good of his country at heart will keep himself well informed on all matters subject to legislation by his representatives and that he will let his opinions be heard and felt when occasion demands.

Time was when the governing class was a distinct and a very small one, and when it was deem-

ed undignified for the medical profession to meddle in such matters. That system may have had its advantages under the old forms of government, but in the grand experiment of self-government, which is being carried out in this western world, the duty of every man, be he physician or not, is to feel and assume his individual responsibility as a citizen in its highest and most important and best function. If that were done there would be no occasion for politics to be synonymous with fraud and dishonesty.

I conceive it to be the duty which the medical profession in this country owes to itself, and to the community, to endeavor to have a larger representation in our various legislative assemblies. Questions relative to public health, sanitation and hygiene are constantly before these bodies for consideration, and for their intelligent action they should have the counsel and advice of those who, by training and education, are best prepared to give it. It cannot be derogatory to the dignity of any profession to thus put itself and its accumulated experiences at the service of the State, and, by so doing, in the proper manner, it elevates itself in the opinion of the community, and, by this added respect, is enabled to work to greater advantage in its own special field of activity.

It was not Virchow's scientific work alone, great as that is, which made him president of the last International Congress, but the reputation he had earned as a man of affairs and the ability he has always displayed in dealing with men; and it is the qualities which have made him conspicuous as an Italian senator and statesman, which will make Baccelli president of the next Congress, which meets at Rome. And no physician who heard the oration he so eloquently delivered in Latin at the opening of the Berlin Congress but must have felt a thrill of pride in the thought that this man of culture was a member of the same profession as himself.

Culture is power. It is the power which moves civilization onwards, because it is not only knowledge acquired, but knowledge refined, assimilated and properly adjusted to all other knowledge and to the higher requirements of our more complicated life. And I claim that the more freely we mingle in the affairs which affect and pertain to man in the mass, the more our sympathies and the higher parts of our nature will be elevated and the broader will be the view we take of those things which belong to the daily work of our lives.

When we look to find the highest development of man in his physical and mental attributes we are led at once to ancient Greece. Never in the history of the world has there been presented finer types of men, singly or collectively, than at that period when Athens was truly the center of the world. To the Grecian of that era the welfare of the State was the first thought, and his greatest ambition was to serve her in any capacity.

Greece's philosophers were also her soldiers, and her soldiers her philosophers. Her statesmen were her scholars, and her artists took the javelin or the chisel indifferently as the needs of the State demanded. Sophocles was not only the writer of the greatest tragedies the world has ever known, but was also a senator and served, as a general with Pericles in the Samian war; and Socrates, beginning life as a sculptor, did his duty with conspicuous bravery as an Athenian citizen, at Delium and Amphipolis, and by his personal courage saved the life of Alcibiades at Potidæe. The Grecian of culture touched life on all sides and the result was that he grew in all directions and became a symmetrical being, and intellectually the model for men of all time. The law of intellectual growth and development is not different to day from what it was in the time of Socrates, Xenophon, Aristotle, Sophocles, Phidias and Pericles and the hosts of others who laid the foundation stones upon which we have builded our structures in philosophy, in literature, in art and morals and to a large extent, our modern science, in which latter alone it is that we can claim any sort of superiority. If we wish to grow mentally we must enlarge our intellectual horizon,—we must open up the ways into the many and various avenues of thought and experience. We must give every faculty its full power of development by furnishing it, as far as in us lies, with a suitable opportunity. That is what was done in Greece on a system more extensive than has ever been tried elsewhere, with the result that the individual as a whole was developed to the farthest extent of his power and capacity. After all, the function of all good government is the protection of the individual, and that is the best government in which, in its truest sense, the individual is allowed the fullest scope for the exercise of all his mental powers. In this system there is much less danger of having "lop-sided men," except as natural deformities. This is, perhaps, an ideal state, a Utopian conception, but if it were attainable in a large measure in a past civilization, we should not despair of its realization in this one which offers many additional advantages for the attainment of that end.

It is, of course, understood that I am not advocating the mingling of the physician in the wrangle of political strife, as we too commonly see it. Much of that is not seemly for any man of refinement and culture, but, if we would change all that, and I conceive that it is our duty to work to that end, we should let the hand of the physician be felt as a citizen in the workings of the machinery of government, whose sole object should be the greatest good to the largest number. But organized Society, such as we would have it, embraces much besides the matters of mere legislation, and there are many other duties and obligations which man owes to the community, in its

minor and subsidiary organizations. The question of education in its broadest sense, the preparation intellectually and physically of the youth for the battle of life, is one of the greatest importance, not only to this, but to all the succeeding generations. The institution of the Church and of societies of various kinds for ethical and moral advancement, and all organized charities for the relief of human suffering, are provinces in which the physician is above all men best prepared by his life training to work with wisdom and judgment. Every school-board should have a representative of the medical profession upon it, and nowhere is the broad humanity of the true physician felt more than in those congregations of men instituted for the cultivation and advancement of his moral and religious nature; and even in our boards of trade he should find his place beside the lawyer and the merchant. And when it comes to public charities there is no one better qualified both by his technical skill and general qualifications to advise than the doctor. In the special matter of hospital management it would appear to the unbiased observer that he was the one *par excellence* to whom should be intrusted the control of all matters pertaining to the care of the sick and the internal management of the hospital generally. And yet there is an opinion current among the lay members of hospital management that the medical man has not enough business capacity to attend to matters which pertain directly to his professional duties, and some hospitals have even gone so far as to make the fact of a man's being a practicing physician a disqualification for service on the board of hospital direction. This is something more than a slur on our profession. It is a hindrance to the proper and best results of hospital treatment, and has led in many instances to an enormous waste of monies that were needed to carry on the legitimate functions of a hospital. It must be confessed that we of the profession are largely responsible for this state of feeling towards us. We have neglected to make ourselves felt as men of affairs and it has reacted upon us in hampering our power for good in our own special line of work. There was never a greater mistake than to suppose that because a man is engaged in the practice of medicine he has thereby lost his power of judgment or faculty of drawing conclusions from facts. It may be true that many, if not most physicians do not manage their own business affairs to the best advantage—for themselves; but that is more largely because of their liberal-mindedness and charity than for want of capacity. It is true they are not schemers, apt in the laying of plans on the hazard of success, indifferent as to the general effects and the final results, and are not skilled in the process of over-reaching, which seems, in the eyes of many, to constitute true "business ability," the "ability" too prevalent on the mart and in the street. The training of

their profession has taught them caution, has taught them to avoid haste in drawing their conclusions until all the data are in, but has given them, withal, the courage to act firmly and promptly on their convictions when they are once formed. Wherever a special pleader is wanted, wherever a champion for partisan aggrandizement is in demand, where bigotry is to be upheld, it must be confessed, that the training of the medical man in his earnest and constant search after the truth but badly fits him for a position of prominence. He cannot compete in these fields with others whose training has been otherwise.

It has been the custom in certain quarters to consider the doctor more than ordinarily deficient in executive ability, as lacking in the power to deal with masses of men and with diverse and widely separated interests. In refutation of that charge we can point with pride to the management of the medical departments of the army and navy throughout the civilized world. In no point of organization or efficient working has the medical department of either arm of the service been behind that of the line, and there was developed, during the late civil war, an amount of ability in the medical staff, which, if it had been surrounded by the glamour of arms, would have made many of them heroes of renown ranking with the first. Wherever courage, coolness, and the shifts of expediency, and a commanding example are needed, we have a representative of our profession. In the ice-locked regions of the north we have a Kane, and an Ambler; and in the wilds of Africa a Livingstone, an Emin and a Parke. And indeed, everywhere where the faculty to organize or the ability to execute is needed, as in the management of our colleges, libraries and museums, we find it forthcoming in the medical man. And yet a collection of second or third-rate lawyers and ordinary tradesmen will assume that in the management of a hospital the men who do the work for which the institution is founded, and without whom it would be a mere pile of bricks and mortar, and who are more conversant with its needs and requirements than any other men could possibly be, are incompetent advisers in its direction. In the conditions of society at one time existent in Europe it was questioned whether a physician might be a gentleman, but in this country, in some minds, there seems to be no doubt as to his being an idiot. And for this general and current opinion I claim that we, as members of the profession, are to blame. If we mingled more in the affairs of common life, and took a more active part in the management of its concerns, the capacity of the medical man to deal with matters other than those purely professional would soon be impressed upon the community, and our opinions on those matters which are of general interest would have the respect and weight given to them which they are deserv-

ing of. To place ourselves, as individual members of a learned, liberal and scientific profession, upon such a plane, I conceive to be a duty we owe to that profession and the Nation, and to ourselves.

But aside from these general obligations and responsibilities as citizens, there are other opportunities of widening our minds and increasing our breadth of view. The day has gone by when, unless he would lose caste in the community, a doctor must be nothing beside a doctor, with his knowledge limited to what he knows of diseases and the remedies therefor. That tradition should have passed away with the gold-headed cane and creaky boots which were the outward token of the physician fifty or more years ago. The barriers between special and general knowledge have been overborne by the coming of the higher culture which finds the necessity for an extent of accomplishment which is not attained by knowing everything of something, even were that possible. To know something of at least a great many things that are worth knowing, is the surest road to knowing everything that can be known of any one thing. Human knowledge on any one subject is not so circumscribed that it cannot be illuminated and made clearer by the light thrown upon it from the knowledge of other subjects outside. The man who makes clay pipes can make them better if he knows something of the laws of chemistry and physics, and can convert them into objects of beauty if he has cultivated his æsthetic sense. Of all the so-called liberal professions I think that of medicine is the only one that can be properly thus named. The law is hampered by statute and precedent, and the Church has no existence if not based upon tradition. Ours is the only one which bids defiance to tradition, boldly questions authority and sets precedent at naught. There is absolutely no intellectual restraint upon us. Our goal is Truth, and to attain to it we may follow any path that seems open and inviting. And as all roads were said to lead to Rome, so I think all knowledge sends its quota to the practitioner of the healing art. Nothing can come amiss to the scientific practitioner—all knowledge can, in one way or another, be made available. It is not only wise, then, but our imperative duty to open up as many of these avenues of culture and wisdom as is possible.

In conversing with a medical man, some time ago, on this topic, he said he did not like doctors for companions because they were so narrow. I disagreed with him *in toto*. There are, of course, doctors and doctors, and, particularly under our American methods of education, there are, unfortunately, a large number of physicians, who are such in name only. But even under our pernicious system, I claim that the average doctor is the peer in intellect and culture of the average man in any other profession. But what I claim

for, and demand of him is that, on account of his better advantages and more enlarged opportunities, he should be superior. "But," the thought instantly arises in the minds of many among you, "we are so engrossed in the toil of our strictly professional activities that we have not the time for the pursuit of this culture." My friends, time will always be found to do the things that we earnestly wish to do. The great difficulty in this case is, that we fail to see the desirability and need of it; and if I shall have been able through this presentation of the case to arouse in you some serious thought on the subject I shall consider that my speaking has not been in vain. I hold that a man who knows medicine and nothing else cannot know that as it ought to be known, and I am not one of those who deem it derogatory to a member of our profession that he should, even openly, vindicate his claim in other fields of culture, whether it be in science, literature or art. In other special fields of intellectual activity it is by no means uncommon. Because Gladstone is one of the greatest statesmen of the age it does not lessen the value of his opinion as an authority on Homer, and a single review by him of a work of fiction is sufficient to give it the widest popularity. Professor Tyndall goes home from a lecture on the latest discoveries in science at the Royal Institution, to write an article on the Irish question, and Mr. Ruskin—well, it would be hard to say what Mr. Ruskin has not written on—and entertainingly and well. The medical man has just as much time to give to the cultivation of these outside subjects, apart from his strictly professional work, as other men, and when we once have the sincere desire for it, the opportunity will not be lacking. It is true that our profession is considered the least regulated of any. Other men are considered to have some time which they can call their own. Not so with the doctor. And yet, even in so exacting a field of labor as ours, a great deal may be accomplished by a proper system. With us, as with other men, the busiest is always the one who has the time to do the thing to be done. It will not be supposed for an instant that I am advocating general culture at the expense of strictly professional study. That should always come first and, with every conscientious man, will have primary consideration always. But the human mind is not a machine that can be worked in one groove all the time, and its best and most satisfactory rest is change. It is said of John Stuart Mill that when he took a vacation he wrote an article on political economy, and in fact all his enormous production in the fields of politics and sociology was done outside of his hours at the Indian Office, which were as exacting as those of any Government office in this country. Lord Beaconsfield, whose career as a politician and diplomat was as brilliant as it was remarkable, is said to have remarked on one oc-

casion that when he wanted to read a novel he wrote one. It is these hours of freedom from professional work and care which are so necessary for the maintenance of clear perception and sound judgment that can be advantageously given to the cultivation of these tastes for general and comprehensive knowledge—tastes that have characterized the vigorous and advanced minds of all ages. There has been in those minds an aspiration for knowledge and a desire for development which has surmounted all obstacles, and they have not grown in one direction at the expense of another. The mind, like any other organ of the body, is rendered stronger and more supple by constant and regular exercise, and is weakened or disabled by irregular, unsystematic or forced action. It is worry and not work which wears out, and to have some congenial occupation into which to divert the mind when it is liable or likely to be overburdened with work, is the best safeguard the brain worker can have. That man is always safest who has a hobby—and who does not trifle with it. A hobby conscientiously pursued, as every genuine hobby should be, is always a serious matter—to the one who follows it, and in that seriousness lies its power for good to him. It is the one thing in the world which he values more than time or money; and, in the rush and crush of modern civilization, anything that restrains avarice or clogs, even temporarily, the whirling wheels of time so as to allow a man to think of something which does not lead to material gain, is a boon to society as well as a salvation to the man.

I am always inclined to be suspicious of a man who has no hobby and who takes no interest in anything outside of the narrow field of labor which has by accident fallen to him. And of all men the doctor is the one who needs such diversion most. He less than any other, should be narrow and restricted in his resources, or allow himself to fall into the slough of despond, or sink beneath a load of responsibilities. There are so many paths leading outward that hardly any taste, but can find some congenial pursuit. If it be that books do not attract, there are paintings, etchings, engravings, bric-a-brac and other object of art and virtue, the study of some favorite branch of science; the practice of some art—as drawing, painting, or sculpture, or some literary pursuit, as the writing of fiction, or of essays on social, literary and scientific subjects, or poetry, when that gift is in possession; the practice of the art of music, vocal or instrumental; in fact, there can be no occupation of the mind which is serious and requires the acquisition of some special knowledge, or which cultivates the finer qualities of our nature, but, in one way or another, can be made of practical utility in the practice of our noble calling. For, let the fact sink deep into the hearts of us all, we do good to

our patients as much by what we *are*, as by what we know of their diseases. The man helps quite as much as the physician, oft-times more.

The history of our profession is not without brilliant examples of such cultured men—of men who, in addition to high professional attainments, have done most acceptable work in other fields of intellectual labor. Mr. Seymour Haden is not any the less a surgeon of ability, because he is the most renowned etcher since Rembrandt, and it was during one of those forced vacations occasioned by overwork that he published in Paris that set of plates which, actually, in one day made him famous; and Sir Henry Thompson is quite as well known in the literary and artistic circles of London as in the surgical society.

In this country we are always proud to mention among others in this connection our own beloved and inimitable Holmes, and Weir Mitchell, who, not only is a great authority on nervous diseases, but ranks high as a general literateur and poet. The list could be largely extended, and you can each call to mind men of your own acquaintance who either have done, or are capable of doing most creditable work in fields which are only remotely connected with the practical art of their profession.

But if I were called upon to designate the man, who, more nearly than any other that I have known, fills my conception of the ideal physician, I would mention the name of one who is still living and passing his declining years in dignity and peace among the beautiful hills of Southern England. There is probably no man within the sound of my voice to whom the name of William Bowman is unfamiliar, certainly no man who studied medicine twenty or thirty years ago. His researches in anatomy and physiology in his earlier years placed him in the front rank in both of these departments, and his achievements in general surgery, before he was actually forced into ophthalmology by his acknowledged superior skill in that specialty, are such as to give him prominence in that line, and in the pathology of that period his name will always be found associated with thoroughly accurate and scientific investigation. There was no man of his time who, by thorough training in the principles of medicine and surgery, actual knowledge of anatomy and physiology, was better prepared than he to take the part he did in founding modern ophthalmology. When the genius of Helmholtz threw the light of the ophthalmoscope upon the world it revealed three men, who, each in his different way, was destined to have his name associated with ophthalmology for all coming time. One was the great clinician at Berlin, the youthful von Graefe; another a physiologist in Holland, the late lamented Donders, who laid the foundation for our clinical optics; and the other was William Bowman, surgeon at the Moorfield

Ophthalmic Hospital in London. These three men were not only the founders of the most advanced and scientific department of medicine, but intimate personal friends in the most ideal way. The work of the two first named is more widely and generally known than that of Bowman, perhaps, for they both wrote extensively, but the lasting impress of Bowman upon the men of his time, and upon succeeding generations, is certainly equal to that of either of the others, and that, as much by the personal character of the man, as by the ability of the surgeon and teacher. No one who has stood, as I have, day after day, by his desk at the great clinic at Moorfield's, and heard his careful and logical analysis of cases, and the lucid explanation of complicated conditions, and has followed him to the amphitheater, and seen him operate with skill of brain and deftness of hand, but must have been impressed with the fact that here was a man who had not only cultivated all his faculties widely, but had them under his perfect control. He must have felt instinctively that this special ability was based upon a broad culture, and that back of it all there was the well-rounded character of the man.

When I was in England, something more than a year ago, it was my pleasure to meet him again on his invitation at his charming country place in Surrey, and the memory of those hours will always remain among the most treasured recollections of my life. It was one of those exceptionally lovely August days, which sometimes come in that English isle, when the brightness of the sky and the rich greenness of the fields combine with the softness of the air to make the perfection of climate. We talked of many and various things, and there was revealed to me in this discourse, more than ever before, the cause and reason of his greatness. A few years before his queen had honored herself by conferring a baronetcy upon him, but long before that the profession to which he had given the best labor of his life had ennobled him with its enduring trust and reverence. He had retired from the active practice of his profession, but his interest in all things pertaining to its advancement was as earnest and eager as in those years when he was at the head of ophthalmology at the world's capital. As we sat there that balmy afternoon on the grassy slope facing the south Downs, with a silvery strip of sea stretching beyond, on which ever and anon the sunshine showed the glint of a passing sail, the discourse drifted into diverse channels, breadth of view and extent of general knowledge, which made him the man he was. He talked of the political situation in the United States with which he was familiar, of our form of government, its strength and its defects, without cynicism, or the pessimism, which so frequently mars the latter days of some otherwise great men. In a modestly apologetic manner, because he

thought that my interest was genuine, he went over the history of his earlier medical education and told me how his choice of the study of medicine, was an accident caused by an injury to his thumb while a school boy at Birmingham. He was attended by a Mr. Hodgson, a celebrated surgeon of that city, and was so charmed by the personality of the man and the skill with which he treated him, that after the custom of that day, he asked to be apprenticed to him, and very soon afterwards entered the Birmingham Hospital. The character of the man was here fore-shadowed in the youth. He showed me afterwards in the library the notebooks he made during those years of hospital work and study with the carefully detailed clinical histories of the cases and the accurate drawings of the pathological conditions found, which could almost be said to represent a complete history of the surgery and pathology of that day. For several years, I think he told me, he either made, or was present at every autopsy during his stay in the institution. What a groundwork on which to build the enduring professional career that followed; and what a lesson in patient industry for the medical student of our day, and what a rebuke to the aspiring specialist of this era who ventures upon his work with only the merest smattering of the general principles of either physiology or pathology and with no experience in the practice of general surgery. But mingled in with these were the sketches which he had made of the places of interest he had visited during his vacations, for he loved to enlarge his mind with travel and to mingle with men of pursuits widely separated from his own. Among his friends were all the literary, artistic and scientific men of prominence of his time.

He talked of Graefe and of Donders, who went from his house only a few months before with the illness that finally led to his death, of the medical men of the past and the younger and more promising men of to-day. His thought had reached out in every domain in which intelligent humanity holds any interest, whether of men, of books, or of affairs. And he was at home in all matters pertaining to literature, art and science. And as I regarded this man, passing thus, in dignified repose, his evening of life, amid the flowers which he had gathered from all quarters of the globe, and which he attended with such loving hands, I felt it the fitting rounding up of a life as nearly ideal as our humanity can offer, and I tried to take the lesson to my heart, that I now offer to you, that the highest usefulness in life can be realized only by a cultivation of all the faculties of our minds on the broadest scale and in the most liberal manner.

But aside from these general considerations and in addition to the benefit to flow to the community from our increased possession of human sympathy and mental enlargement, there comes

to the individual by a cultivation of those higher faculties, a respect for himself and an increase in his sources of pleasure, and a widening of his capacity for enjoyment which nothing else can bring. To the man with a broadly cultivated mind there is no time or place, with freedom of mind and body, when he need suffer from ennui. He is ever prepared, alike, for work or recreation. To him the world offers always its best, and it is to be had for the taking. To him Nature lays bare the beauties hidden from the eyes that have not learned to see. The artists of all past times have wrought their ideas into lasting forms for his pleasure, and the accumulated literature of all ages is at hand for his instruction and entertainment. The processes of civilization as seen from his higher vantage ground have a unity, a relation and a connected purpose to an end which are in gratifying and hopeful contrast to the workings of the world as seen from the lowlands of narrowmindedness and desponding and despairing wonderment at the apparently purposeless scheme of the universe.

But, my friends, in the garment of life which we wear for this brief season here upon earth, there must needs be not only the warp of joy but also the woof of sorrow. The sun of prosperity and peace shines not always, and in the lives of all of us there are periods when the dark clouds of despondency cast themselves athwart his smiling face. In the course of nature there must come times when the sky is no longer blue, and the sunlight has lost its brightness; when the color has faded from the flowers and there is no music in the laughter of children; when affliction takes up its abode on our hearth-stone, and when grief becomes our constant companion; when life means only the beginning of death; when we stand alone in this vast universe with no human hand to sustain and the arm of God seems afar off. It is then that we must look within for that power which must hold us up if we would not fall. It is then that our higher manhood, with its understanding widened by culture and deepened by sympathy, and the aspirations of that which makes us what we are, give us glimpses of what the awful Mystery may mean, and the light of Duty shines upon the path we are to follow. It is that only which can save us from despair and give us the courage to live and to do as faithfully as we can the work that is at our hands to do. The world wants not less now than it has ever done, that courage and that faith which can only come from the liberal culture of the nobler and higher elements of our nature, and nowhere can they work for greater good than in the daily duties of the profession which it is our honor to follow. There is need not only of physicians, but men; and the nobler the man the greater the physician.

ORIGINAL ARTICLES.

A PLEA FOR EARLY VAGINAL HYSTERECTOMY FOR CANCER OF THE UTERUS.

Read in the Section of Obstetrics and Diseases of Women, at the Forty-first Annual Meeting of the American Medical Association, held in Nashville, Tenn., May, 1900.

BY FRANKLIN H. MARTIN, M.D.,

PROFESSOR OF GYNECOLOGY, POST-GRADUATE MEDICAL SCHOOL; SURGEON TO WOMAN'S HOSPITAL, CHICAGO.

It is, at present, a generally conceded fact that cancer can be permanently eradicated from the human body if the parts of primary development and subsequent invasion can, early in the progress of disease, be absolutely separated and removed from the surrounding normal tissue. This implies that the operation for cancer which will go the farthest beyond the diseased limits, is the one most liable to accomplish absolute removal, consequently the one by which the most satisfactory curative results must be expected. With this fact well established, we can have no hesitancy in making the assertion that the operation which will obtain the best ultimate results in cancer of any portion of the uterus is the one which will accomplish its total removal, together with as much of the tissue which lies in close proximity to it as can be removed without unduly increasing immediate mortality.

Hence my first proposition is: *Vaginal hysterectomy is the most justifiable surgical procedure we yet know for the cure of cancer of the uterus.*

A second fact which is as incontrovertible as the first, and one made obvious from the very nature of the first, is that the earlier cancerous tissue is removed in the process of its development, the greater are the probabilities of a non-return of the disease. Hence my second proposition:

Vaginal hysterectomy should be attempted for the cure of cancer of the uterus, at the earliest possible moment after the disease is diagnosed.

Thus it shall be the effort of the author of this paper not only to convince his hearers that vaginal hysterectomy is the most justifiable operation for cancer of any part of the uterus, but that it is an operation which should be resorted to early in the progress of the disease.

The facts to be proven in support of these propositions, in order to make them acceptable, must be as follows:

1. That vaginal hysterectomy will remove the entire disease in cancer in any portion of the uterus, in a greater proportion of cases than will any other surgical procedure now recommended.
2. That vaginal hysterectomy for cancer of the uterus will enable an operator to go farther beyond the diseased tissue into healthy tissue, than will any other surgical procedure now recommended.
3. That vaginal hysterectomy is a more ideal surgical operation, and leaves the remaining tis-

sues in a less favorable condition for the return of the disease, than will any other surgical procedure now recommended.

4. That vaginal hysterectomy for cancer of the uterus will give in the future an immediate mortality sufficiently low to make it preferred to all other surgical procedures.

1. Will vaginal hysterectomy remove the entire disease in cancer of any portion of the uterus in a greater proportion of cases than will any other surgical procedure?

Let us first examine the uterus, and then the other possible operations which might possibly be selected.

The uterus is divided arbitrarily into two portions, the body and the neck. The body, which represents two-thirds of the entire organ, is supported and suspended upright in the centre of the pelvis by numerous connecting bands, with its two branching arms of tissue, which have a direct continuity with itself, reaching out into the folds of the peritoneum from either side, all covered with peritoneum, all closely associated with other important organs, the rectum behind, the bladder in front, the ovaries on either side, the intestines above and the vagina below, and with an elaborate connecting network of veins, arteries, lymphatic vessels and glands distributed throughout its entire structure.

The neck of the uterus, which in anatomical structure is a direct continuation of the uterus and represents but one-third of that organ, is suspended from its uterine attachments above into the vaginal tube below, where it is free from all direct tissue communication with its surroundings except as it is supplied from the body and the vaginal attachment above.

The operations which may be urged as possible rivals of vaginal hysterectomy: the cautery—chemical, actual, Paquelin or electro—curetting, amputation and abdominal hysterectomy. When it is remembered that at this stage of the paper, we are considering whether vaginal hysterectomy will remove the entire disease in cancer of any portion of the uterus in a greater proportion of cases, than will any of the above named operations, it becomes obvious at once, that the only one which can compete with vaginal hysterectomy at all in this respect is abdominal hysterectomy. It must be admitted, however, that abdominal hysterectomy, when performed so as to remove the entire uterus, including the cervix and Fallopian tubes, will accomplish the same end in the same proportion of cases as will vaginal hysterectomy; but the operation has other disadvantages which are obvious to many which render it inferior to vaginal hysterectomy, and which will be touched upon under the heading of mortality. I do not care to bring an array of arguments to prove obvious facts. I will therefore pass to our second consideration.

2. Will vaginal hysterectomy for cancer of the uterus enable an operator to go farther beyond the diseased tissue into healthy tissue than any other surgical procedure?

The cautery can be employed in these cases to follow out the limits of the disease, if it is confined to the cervix, and possibly the lower portion of the body and any encroachment on the vaginal walls which has not involved deep underlying tissues. Much can be accomplished in cancer of the cervix with this remedy, but when the disease begins to involve the body of the uterus, the dangers of subsequent hemorrhage, from the imperfect closure of those large vessels which must be destroyed in reaching those portions, makes one tremble for the result. When cautery is employed to its fullest extent, however, we are still far short of what is accomplished in total removal of the uterus.

Curetting.—With curetting, from the nature of the instruments employed, we do not expect to go any great distance beyond the friable tissue made so by the march of the disease. Dull curettes do not remove readily, healthy tissue which it is necessary to get into beyond the diseased portions, and sharp ones possess no remedy for the hemorrhage they produce. So, with this remedy, we cannot hope to go far beyond the limits of the disease and never approach anything like the amount of tissue removal that is accomplished by hysterectomy.

High Amputation.—High amputation of the cervix can accomplish the removal of considerable tissue if it is properly performed. The vaginal mucous membrane can be removed to the extent of $1\frac{1}{2}$ to 2 inches from the vaginal attachments. Ligatures may transfix the base of the broad ligament at least an inch away from the uterus and a corresponding amount of tissue be removed. The amputation may extend well into the body of the uterus, and with great care to suppress the hemorrhage, the fundus may be pretty well approached. Here, however, we reach the limit of our possibilities with high amputation.

Abdominal Hysterectomy.—With abdominal hysterectomy the ovaries and the tubes can be removed with the body of the uterus, and by performing a very unusual abdominal hysterectomy the cervix may be included with the body. It would not be practicable, however, for one to remove very much of the vaginal mucous membrane.

Vaginal Hysterectomy.—With this operation the whole upper portion of the vagina to the extent of $1\frac{1}{2}$ or 2 inches from its cervical attachment can be severed at the outset, to be included in the tissues to be removed. After separating well the bladder from the uterus, and carrying the separation well to the side, so as to certainly dissect the ureters from the broad ligaments, the base of the broad ligaments can be ligated well

out to their pelvic attachments, by first drawing the cervix forcibly to the opposite side. When the base of one broad ligament is ligated and the uterus well drawn down upon that side, the large broad ligament lock forceps (Byford's pattern) can be adjusted to the remaining portion of the ligament, and at such a distance from the uterus as to leave the ovary and tube attached to the latter ready to be removed with the diseased tissue. When one broad ligament is severed, the uterus can, ordinarily, be delivered. It is an easy matter then, by commencing to ligate at the upper margin of the broad ligament, which remains intact, to get well away from the uterus, and, by carefully ligating and severing by sections, each ligature being crowded farther away from the uterus, it is possible to get the ligatures, which are applied to the base, well out to the side of the pelvis. To summarize then, without unduly complicating the operation we may, when necessary, remove the following tissues with vaginal hysterectomy: the uterus entire, the upper portion of the vagina for a distance of 2 inches from its uterine attachments, both broad ligaments to a distance of 1 to 2 inches from the uterus, both Fallopian tubes and both ovaries.

Compare with this, what is accomplished with the most thorough cauterization, curetting, or high amputation which can be made. It will be found after these operations, that we have remaining, the fundus of the uterus, the Fallopian tubes, the ovaries and much cellular tissue surrounding them which must be removed in the most ordinary vaginal hysterectomy. The points of comparison are so apparent, and the comparison so favorable to vaginal hysterectomy under this heading, that I feel it superfluous to go into further detail.

3. Is vaginal hysterectomy a more ideal surgical operation, and does it leave the remaining tissues in a less favorable condition for a return of the disease? This interrogation seems to me somewhat axiomatic. I shall, therefore, employ but little time in its discussion.

With vaginal hysterectomy an organ in its entirety is removed. With curetting, cauterizing, or amputation, only a portion of an organ is removed and crushed, cauterized, or cut surfaces of a tissue remains to be cared for which previously had a direct continuity with the diseased tissue. With vaginal hysterectomy satisfactory and safe stumps are secured which contain all bleeding-vessels of importance and also all channels through which absorption of infectious material may occur. With curette, cautery or amputation no regular stumps are secured, and large ugly surfaces of tissue are left exposed which stand ready to absorb infectious matter. To the extent, too, that the stumps are imperfect to that extent is the security against hæmorrhage imperfect. With vaginal hysterectomy the facil-

ities for drainage are almost imperfect, while with the other operations, the very nature of the remedy employed against hæmorrhage, viz.: packing or tamponing may oftentimes interfere with satisfactory drainage.

The above remarks do not apply to abdominal hysterectomy. With this operation, however, we have an additional complication of an abdominal incision, and the responsibility of treating two openings into the peritoneal cavity instead of one as in vaginal hysterectomy. The difficulty of securing the broad ligaments in their entirety from an abdominal incision is much greater than when they are handled from below.

4. Will vaginal hysterectomy for cancer of the uterus give in the future an immediate mortality sufficiently low to make it preferable to all other surgical procedures?

I shall leave the subject of abdominal hysterectomy for cancer out of my calculations here because we have seen that it is really not an appropriate operation for the difficulty under consideration, and also because of a recognition of this fact, in this connection it has been almost entirely abandoned.

In discussing this question I shall take the liberty of assuming, that the older operation—curetting, cauterization and amputation—have for years been out of their experimental stage, while with vaginal hysterectomy, recent statistics only are of any value in determining the future of the operation.

With partial removal of the uterus, or high amputation in the hands of expert American operators, recently reported, an immediate mortality of more than 4½ per cent. has been the result. These represent the fifty-five cases reported by Reamy in 1888, with two deaths or a mortality of 3.6 per cent., and of thirty cases reported by Reeves Jackson in January, 1890, with two deaths or a mortality of 6.6 per cent. This mortality seems rather high for an operation which at its best is considered but a conservative method for treating a grave disease. It is considerably lower, however, than we get from our foreign brethren, for instance: Verneuil in January, 1889, records twenty-two cases, with two deaths, or a mortality of 9 per cent. Hofmeier's table of ninety-six Berlin-cases, gives a mortality of 7.4 per cent. Thus, with the best statistics which can be obtained for the so-called conservative treatment of cancer of the uterus, we must grant a mortality of 3.6 per cent., while with the two best records, a mortality of more than 4.5 per cent. is obtained. In the face of these statistics from expert operators, can I be said to be unfair, if I assume the legitimate mortality of partial removal of the uterus to be at least 5 per cent.?

What is the present mortality of vaginal hysterectomy? The published statistics of this op-

eration have shown a gradual lowering of mortality since 1880. The statistics of all published cases, gathered by Dr. S. E. Post, showed for the cases published before 1880 an immediate mortality of 37 per cent.; for those published in 1880 and 1881 26.5 per cent.; for additional ones to the end of 1882, 27 per cent.; for additional ones to the end of 1885, 24 per cent.; while the additional ones to the end of 1887, gave a mortality of only 20 per cent. The above statistics are valueless to prove the legitimate ultimate mortality of this operation. First, because they contain the records of operators of experience, not only, but also those of scores of operators with their first one or two cases and the result of all their inexperience; second, because these statistics are the records of operations performed while the procedure was in its primitive and experimental stage, and, too, many of the results represent work performed before the establish-

ment of the present antiseptic surgery. In order to get more nearly at the present status of this operation in this country, and to be able to forecast with greater accuracy the future immediate mortality of this operation, I sent circular letters to many of the leading operators of this country requesting them to fill out enclosed blanks with histories of all operations of vaginal hysterectomy performed by them since January, 1885. I received replies from twenty-five operators, representing 134 operations, with 20 deaths, or a mortality of less than 15 per cent. Of the 25 who responded, 4 had operated but once, 3 twice, 2 three times, 3 four times, 5 five times, 2 six times, 1 eight times, 1 twelve times, 1 thirteen times, 1 fifteen times and 1 twenty times.

The average mortality of the four highest operators is just 10 per cent. The operator having the greatest number of operations to his credit, has also the lowest average mortality. The mor-

tality being but 5 per cent. with twenty cases. The operator having the next highest number of cases, has also the next lowest mortality, or 6.2 per cent. in fifteen cases.

These figures are all significant. They show conclusively that vaginal hysterectomy is no exception to the rule, that with experience in operating comes proficiency and lowering of death-rate. They demonstrate, to my mind, that the legitimate death-rate among good surgeons, ought not to exceed 10 per cent., and that the death-rate with the expert will not exceed 5 per cent.

This then, is the burden of my proof: With the best record, in this country, for the so-called conservative treatment, we have a mortality of 3.6 per cent., while the best record for the radical operation is but 1.4 higher, or 5 per cent. With the next best record for the conservative treatment, we have a mortality of 6.6 per cent., while for the radical operation we have but 6.6 per cent. Thus, we find, without any manipulating of statistics, the comparatively new operation of vaginal hysterectomy presents a mortality, which is but a shade higher than the old and imperfect so called conservative method.

I will leave this subject now with the society. I am aware that not all the proof which I have been able to array, in support of my propositions, has been conclusive; they do, however, represent my honest convictions.

GENERAL SUMMARY:

1. Vaginal hysterectomy is the most justifiable surgical procedure, we yet know, for the cure of cancer of the uterus.

2. Vaginal hysterectomy should be attempted, for the cure of cancer of the uterus, at the earliest possible moment after the disease is diagnosed.

The following facts are given in support of the foregoing proposition:

a. Vaginal hysterectomy will remove the entire disease in cancer of any portion of the uterus in a greater proportion of cases than will any other surgical procedure now recommended.

b. Vaginal hysterectomy for cancer of the uterus will enable an operator to go farther beyond the diseased tissue into healthy tissue than will any other surgical procedure now recommended.

c. Vaginal hysterectomy is a more ideal surgical operation, and leaves the remaining tissue in a less favorable condition for the return of the disease, than will any other surgical procedure now recommended.

3. Vaginal hysterectomy, for cancer of the uterus, will give in the future, an immediate mortality among general operators of not more than 10 per cent., while in the hands of experts it will not exceed 5 per cent.

TESTS FOR VISUAL ACUTENESS: THEIR ILLUMINATION; AND THE STANDARD OF NORMAL VISION.

Read at the Session on Ophthalmology at the Forty-first Annual Meeting of the American Medical Association at Nashville, Tenn., May 25.

BY EDWARD JACKSON, A.M., M.D.

PROFESSOR OF DISTANCE OF THE EYE IN THE PHILADELPHIA POLY-CLINIC; SURGEON-CHIEF OF THE PHILADELPHIA DEPARTMENT OF OPHTHALMOLOGY.

The adoption of a definite series of tests for visual acuteness, constitutes an important advance in the diagnosis of ocular conditions. The Jaeger scale and method of notation added greatly to the definiteness of our knowledge. But the work of Snellen brought a further advance, of perhaps equal importance; and his series of test type, and system of fractional notation have almost entirely supplanted their predecessors. Probably most of us have realized that the Snellen system, too, is not perfect; and whether or not we are prepared to at once supersede it, a discussion of its deficiencies, leading to a more exact appreciation of them, will certainly be profitable.

We use tests of visual acuteness for two purposes, the determination of visual power of the eye, and the ascertaining what lens from the trial set best corrects its error of refraction. For the former use we require of our standard that it shall have a fixed and definite significance. Variability and indefiniteness in our standards are absolutely fatal to scientific accuracy. For the latter use we require a test that shall not mislead us into resting satisfied with an imperfect correction when a better one is obtainable.

The observation on which the Snellen scale was based was, that in healthy eyes free from manifest ametropia, two points to be seen as separate points must be far enough apart to subtend an angle of one minute, or a little less. This observation has been abundantly verified, and for the great mass of eyes its substantial correctness cannot be questioned. Snellen, experimenting and reasoning on this subject, came to the conclusions that only a block letter can have all its different parts equally visible, and that to have each of the component parts of a letter visible to the normal eye, each of these parts must subtend the angle of one minute. He also found that in some of the capital letters of the alphabet, as B and S, to make the letter at all complete there must be at least five component parts both vertically and horizontally. Therefore he constructed his test-type on such a scale that each letter should occupy a square, each side of which should subtend an angle of five minutes at the nodal point of the eye.

But the majority of the letters of the alphabet do not require that five component parts shall be seen in order that the letter shall be recognized, O will be recognizable if the angle it subtends is but three minutes, and an L can be constructed

that can be positively identified by eyes with ordinarily perfect vision under a visual angle of about two minutes. Block letters of equal size then, are very unequally visible; to be equally visible, they must be of very different sizes. Dennett carefully worked this subject out, (see Trans. American Ophthalmological Society for 1885), and proposed that the letters on any one line of our test-cards should be made of such unequal sizes that they should really be equally visible, at any given distance.

Other methods of meeting this difficulty have been resorted to. As in a card, published by Bonschur and Holmes of Philadelphia, letters like the O, C, G, and Q, that are liable to be confused with one another, are printed on the same line. In Oliver's, and many other cards, only certain letters are employed, the others being excluded; one author selecting certain letters, another choosing certain others. About three years ago I arranged a card on which the letters were each made to subtend an angle of four and one-half minutes, instead of five, the letters more easily seen being placed at the beginning of each line. And since then cards have been arranged by Dr. Chas. M. Culver, and Dr. James Wallace, with letters subtending an angle of four minutes each.

The card last alluded to, which is published by Wall & Ochs, of Philadelphia, is on the whole the most satisfactory card of test letters that I have used; and yet it is very far from furnishing a perfect standard for the determination of visual acuteness. The raising of the standard does not even do away with hyper-normal vision. Of one hundred consecutive cases of ametropia tested with this card at the distance of *four* metres, after the correction of their ametropia:

1 could read only the 12 metre line; 3 could read only the 7.5 metre line; 3 could read only the 6 metre line; 13 could read only the 5 metre line; 29 could read only the 4 metre line; 24 could read most of the 3 metre line; 20 could read nearly all of the 3 metre line; 7 could read all of the 3 metre line.

That is, 51 per cent. of these patients had vision distinctly better than 4, when tested by letters subtending the angle of only four minutes.

It is possible that still smaller letters would do as well, or even better for practical work with the trial-glasses, but what has been said is sufficient to show that no visual test embracing such varied and complex forms as the letters of the alphabet can give us a standard of such scientific definiteness and accuracy as we have the right to demand. Such a standard is only made possible by recourse to some simple, constant, geometrical figure.

A NEW TEST.

The figure I have chosen for this purpose is here shown.

It is an incomplete square, each side of which subtends the angle of three minutes; the incomplete side being turned in the various directions, and the patient required to indicate its direction. This is based on the same observation as Snellen's test, that points to be seen as separate points must be separated by an angle of one minute, but it furnishes a test that conforms as nearly as any test may to the scientific requirements of constancy and definiteness. A card of such test figures, arranged for use at the distance of four metres, has been published by H. C. Boden & Co., of Philadelphia, and may be obtained of them.

I have also found very useful as a test of visual acuteness that could be carried in the vest pocket, one of these same incomplete squares printed in the centre of a square card. It can be turned in any direction and the patient required to indicate its direction. There is only one chance in four of his guessing right, and a few trials give certain evidence as to the visual acuteness.

I do not offer these tests expecting them to supersede the use of test-letters for the ordinary correcting of ametropia. But if we will use them simply for determining and recording the visual acuteness in each case, we will obtain records of far greater scientific and practical value, than are obtainable with the various letter-tests that claim to be founded on the Snellen basis.

ILLUMINATION OF THE TEST CARD.

The results obtained with the four minute test-type, referred to above, may strike some as extraordinary. But I am satisfied that they will not be found exceptional, provided the ametropia is perfectly corrected, and the *test card well illuminated*. This matter of the illumination of the test-card is not sufficiently appreciated. Probably the greatest harm that comes to us from accepting as normal Snellen's $\frac{5}{4}$, which is often not three-fourths of normal vision, is the tendency it breeds to tolerate an utterly inadequate illumination.

We all understand that the visibility of any test varies with its illumination, but no one who has not worked by a constant [artificial] illumination can appreciate the enormous variations, not only from day to day but even from hour to hour or minute to minute, in the ordinary diffused daylight. Then, under the best conditions diffuse daylight gives a too feeble illumination, unless the card be directly exposed to a large expanse of unobstructed sky, or the reflection of direct sunlight from a white or other light colored surface.

In estimating ametropia with the test-lenses and letters, we appreciate the uncertainty, the widening of the limits of probable error, that come from amblyopia due to haziness of the media, or disease of the retina. Yet very often the

same uncertainty and increased chance of error is permitted through imperfect illumination. In one of the largest ophthalmic hospitals of this country, the surgeons and their assistants have to put down on dark days $\frac{2}{3}$ or $\frac{2}{4}$ as the best obtainable vision for the majority of persons, and are satisfied with any illumination that gives it. There can be no doubt that all refraction work done under conditions where $\frac{2}{3}$ to $\frac{2}{4}$ is the best obtainable vision is vitiated with great probability of error. To render evident the slighter departures from perfect vision, the slighter departures from perfect correction of the ametropia, strong illumination is essential.

Brightness aids in securing practical constancy of illumination. When the light is feeble a slight change in its quantity makes a notable change in the visibility of the test; but as the illumination is made brighter the amount of light that must be added to cause such a change must be much greater; until finally a point is reached beyond which the indefinite increase of the light adds practically nothing to the visibility of the test.

For some years I have used the illumination from an argand gas-burner, placed fifteen inches from the test card. This is brighter than can be obtained by diffuse daylight, except through a large skylight, for a small part of an especially bright day. And a somewhat brighter illumination still would be a little better. Such an illumination is subject to slight variations, but they are quite insignificant as compared with those of diffuse daylight; and the somewhat yellowish color of the light, by lessening irradiation, is very favorable to clearness of vision.

THE CLINIC.

SIMPLE OVARIOTOMY.¹

BY O. G. PFAFF, M.D.,

CLINICAL LECTURER ON DISEASES OF WOMEN IN THE MEDICAL COLLEGE OF INDIANA; GYNECOLOGIST TO THE INDIAN-APOLIS CITY DISPENSARY ETC.

Gentlemen: What I shall have to say to-day concerns chiefly *simple methods of work* as applied to the general run of cases, and it is not at all designed to be a detailed description of the work of any particular man. On the contrary, I have seen many operators at work and I think I can see that those whose operations are marked by rapidity and simplicity obtain the best results; and it shall be my aim to simply emphasize certain points which observation and experience have taught me, constitute the first principles of intelligent clear-headed work, and the key-note to success.

In undertaking any operation wherein the ab-

dominal cavity is to be invaded, we should have as a part of our equipment, two basins; one to contain a very few instruments which are always required, the other to contain those which may be needed; many cases will be thoroughly well done, and quickly too, by means of a scalpel, a grooved director, a pair of dissecting forceps and a Hagadorn needle; but in the complicated cases our supply must equal the demand; the best rule is to use one instrument for as many purposes as due regard for efficiency and economy of time will permit.

Make a quick incision, taking care not to cut too deeply, aiming directly for the linea alba, which is the line almost universally accepted as the only proper route to the peritoneal cavity; however, I believe it makes no difference, and the only reason for making the cut through the linea alba is, that it chances to be the median line, and therefore most naturally invites incision. If the linea alba be not directly reached, authorities generally agree that we should carefully dissect for it; to do so is but to sacrifice precious seconds without the possibility of any compensation whatever; on the contrary, it but complicates the first steps of the operation; there is more bleeding from the muscle wound than occurs from the regulation incision, but this is of no consequence at all as it is instantly and perfectly controlled by compression forceps. This incision has a positive advantage in healing, for as Dr. Robert Morris truly says, a cut through muscular fibre heals much more readily and firmly than does a cut through fibrous tissue.

Having reached the peritoneum, picked it up with the dissecting forceps, knicked it with the knife which you have not as yet laid down, it is to be opened on a grooved director with the same knife to the extent of the external wound; in a very large majority of cases it is by this time apparent whether the abdominal wound is to be enlarged or not; in case it is decided to extend the cut, it is the custom of most operators to do so by means of scissors, protecting the abdominal viscera from injury by a grooved director guiding the under blade. A quicker, neater and more surgical way is to simply insert two fingers through the abdominal wound, letting them occupy a position directly beneath the line of proposed incision, and with the knife, still held in the hand, with its point following the groove between the two fingers, enlarge the opening to the extent desired, above and below.

After evacuating the cyst, with the patient always on her side for this purpose, and the cyst wound again closed with catch forceps, the adhesions must be attacked with the utmost determination, as there is but one rule; they must be broken up; and we are justified in using a great deal of force to accomplish that most necessary result, even if the bladder or intestines be torn as

¹A paper upon this subject was read before the Mississippi Valley Medical Association, Oct. 10, 1890.

the result of determined effort at separation; these injuries properly repaired and the cyst completely removed, the woman's chances for ultimate recovery are far brighter than they could possibly be were the cyst allowed to remain and the vain attempt to cure by drainage made; such attempts amount simply to tapping and end in disappointment and disgust.

The enucleation of certain tumors is practicable and may be resorted to as the quickest and safest method of removal; I am aware of the fact that when adhesions are very extensive and firm there has usually been inflammation of the cyst and that its layers cannot be separated, but in a recent case where I had undertaken the removal of a large multilocular cyst, the woman having had several attacks of peritonitis, I encountered adhesions so extensive and firm that it seemed impossible to break them up without the almost certain result of serious damage to the abdominal viscera; I made the attempt to enucleate, and the ease and rapidity with which I accomplished the maneuver amounted to a positive delight.

In treating the pedicle, the clamp is more often a hindrance than a help, and should be dispensed with whenever it is possible to do so, its application and removal consumes valuable time and its employment does not simplify the operation.

The pedicle is to be tied in two or more sections by crossed ligatures of No. 11 braided silk, prepared for the purpose by six hours immersion in melted yellow wax, according to Skene's method.

The simplest manner of introducing the ligature is with a slightly curved Hagadorn needle held between the thumb and finger, although the small ligature forceps of Keith are convenient, and also those of Cleaveland. When securely tied and neatly divided, the edges of the stump will be everted and curl back over the ligature forming a capsule for it, thereby effectually disposing of the question of subsequent irritation as far as that particular ligature is concerned.

Following the removal of a tumor, or diseased ovaries, or the performance of any other abdominal work, the cavity is to be thoroughly flushed with strained, boiled water at a temperature of several degrees above that of the blood, poured in a strong stream from an ordinary pitcher, as this can be more rapidly done than if the fountain irrigator be employed; and also in the pitcher we have constantly presented for inspection the whole quantity of water to be used, this is of practical importance as I have known of a fly to drop into the fountain reservoir, the mouth of which had been carelessly left uncovered.

This irrigation should be practiced in every case, no matter how simple the operation nor how clean the cavity, and I believe that in a large majority of instances, the chief benefit to be derived from this process of hot water irrigation comes of the fact that it prevents shock or counteracts its effects.

While assistant to my preceptor, the lamented Harvey, whose proportion of terrible cases can scarcely be matched, and who, as an operator, judged by the results in *such cases*, had few peers, and no superiors, I have seen the hot water poured into the pelvic cavities of patients in a state of collapse from the effects of the prolonged and complicated operations, and these patients had the scale turned at once in their favor and most of them got well when they would otherwise, many of them, have undoubtedly succumbed immediately to the effects of the operation. If it does so much in such cases as were Harvey's, the use of hot water in simple cases is but to insure the lives of our patients.

In closing the abdomen, the Peaslee needle or some modification of it is very generally used, but I think this is because of the tardy arrival of the Hagadorn needle; the clumsy "see-saw" motion necessary with the Peaslee needle has driven it from the perineum and it is but the result of progress that it should take its place along with silver ware on the retired list with full honors, to be called on for service only in time of emergency.

I have devised a needle forceps which will hold a Hagadorn needle of any size, straight or curved, at any angle desired. With this instrument I grasp the slightly curved No. 2 Hagadorn needle near the eye, holding it directly on a line with the instrument, and push it through the abdominal walls, completing the suture as in any other wound; I believe a still better method is to hold the needle between the thumb and finger, passing it directly through as described without the aid of any forceps whatever, this is my custom in suturing the perineum, and I have tried it in laparotomy with much comfort.

The sutures and dressings which I have adopted are both Skene's, and are described by him in his recent work, however, I will give a few points which I received from him.

Braided silk is used for all sutures and ligatures in this and all other surgical operations; its chief merit lies in the fact that braided silk cannot untwist, because it is not twisted, therefore its fibers cannot become separated thereby favoring the accumulation of blood clots or other debris which might decompose. The proper size for the pedicle is No. 11; for ligating strong adhesions or large blood vessels, No. 3; and for the abdominal walls, No. 4.

The braided silk is prepared for use by the surgeon himself; or a super-conscientious assistant. I first wind it loosely around a small, clean piece of pine wood, the diameter of a pencil and three or four inches long; it is then put into a small basin with sufficient yellow wax (which is more pliable than white wax) to cover it when melted; it is then placed in a hot water bath where it must remain for full six hours, this time

being required for the thorough saturation of every fibre with the wax. The silk is now to be drawn through a carbolized sponge to remove the surplus wax, when it is to be wound upon suitable spools and kept in a closed bottle; silk so prepared is absolutely aseptic, and so far as its body is concerned it must remain so, as it can no more absorb anything than can silver wire; when removed after the healing of wounds and examined by experts, the silk has been repeatedly found to be still aseptic; for the sake of insuring an aseptic condition of the surface of the sutures, they must be placed in antiseptic solution at the time of the operation just as is the custom when silver wire is employed.

In tying the sutures it will facilitate the work to first smear the portion which is to form the knot with a little purified vaseline.

The dressing is, I think, perfection, both in simplicity and efficiency: no iodoform, no bismuth, no oiled silk, nor patent protectives of half a dozen layers, but simply one square yard of ordinary cheesecloth boiled, and then soaked over night in a 12½ per cent. solution of carbolic acid in glycerine; wring this out with the hands when it is to be used, fold it to a convenient size, about 6x10 inches, adjust neatly over the wound, cover it with a good thick pad of cotton and apply an ordinary binder; when this dressing is removed at the end of a week, it will be as sweet and clean as when first applied.

The after treatment is as important as it is simple and should be commenced before the operation; that is a saline laxative just before the anæsthetic securing an action of the bowels directly after the operation, and I insist on daily evacuations for at least four days, thereby providing most efficient drainage, preventing fever and abolishing pain.

Fever and pain generally mean sepsis, and drainage by the bowel is the remedy, not quinine and opium. If in spite of everything, serious, general peritonitis should supervene, and refuse to yield to the free administration of salines, the patient is entitled to one more chance, open the wound, wash out the cavity freely again with hot water, suture it closely and apply a fresh dressing.

For extraordinary and persistent pain I give anodynes, and for very high and stubborn fever I give antipyretics, but in the main patients suffering from the effects of operations must be treated mechanically, and if they cannot be saved by such treatment they must die.

PRINCE ALEXANDER OF OLDENBURG has contributed a sum of 400,000 roubles (about \$230,000) towards the establishment of a hospital for patients suffering from tuberculosis in St. Petersburg.

MEDICAL PROGRESS.

Therapeutics and Pharmacology.

CREOLIN. — In an inaugural dissertation at Breslau, in 1890 (*Centralblatt für Gynäkologie*, II), BITTER gives a résumé of the use of creolin in over two thousand puerperal cases in the Breslau Lying-in-Hospital. In three women who were having uterine douches of creolin solution symptoms of intoxication suddenly appeared, such as anxiety, nausea and fainting. All complained of a taste of tar or smoke in the mouth. The taste was persistent for a time, but the other symptoms disappeared immediately on interrupting the douches. A fourth woman was very restless and felt weak for several days. Thirty-six hours after the attack in these cases, the urine drawn with catheter was dark brown and contained albumen. The color disappeared in a few days, but the albuminuria persisted for a short time. The author favors creolin on account of its anti-bacterial properties and its relative harmlessness to patients. It is a good deodorizer, irritates the skin, mucous membranes and wound surfaces but little. It has no anti-hemorrhagic action. Its disadvantages are that the solutions or emulsions are not transparent, and the preparation is not always reliable.

KOCH'S TREATMENT IN LUPUS: FATAL RESULT. — JARISCH (*Wiener klin. Wochenschr.*, No. 50, 1890), gives the following details of the case of lupus in which death recently followed the injection of Koch's fluid at Innsbruck. The patient was a girl, aged 17, who had been under treatment in the Dermatological Clinic for a year and a half for lupus exulcerans of the face. The general state of nutrition was good. The skin of the face was for the most part transformed into a reticulated scar, isolated lupus nodules projecting in the meshes of the cicatricial network. The alæ nasi were completely eaten away, the nares narrowed so as barely to admit a quill, the mouth narrowed so that examination of its interior was impossible. There was ectropion on the left side; the cervical and submaxillary glands were enlarged. Examination of the thoracic and abdominal organs gave negative results; there was no albumen in the urine. On December 3, at 9.30 A.M., an injection of 2 milligrams of carbolized Koch's fluid was given. Local reaction was very marked. During the rigor the lupus scars on the face became livid. About 3 P.M. the lower parts of the face at the edges of the cicatrices became swollen, the scars themselves being surrounded to the extent of a finger's breadth by a bright red inflammatory halo. The cheeks and nose showed no marked changes, but the upper lip was livid. About 5 P.M. all the cicatrized parts were swollen, tense, and surrounded with

the intense red zone as before. The lupus nodules appeared more prominent and were bright red in color, most of them being still isolated, but their inflammatory halos were confluent in some cases. At 9 A.M., on December 4, the swelling and redness were more diffused, the whole of the face being involved, especially in the lower parts. The bright red had given place to a livid color. In addition to the other ordinary signs of local reaction, it was noticed that the ectropion was markedly diminished; and the conjunctiva, palpebral and ocular, of both eyes was intensely red and secreted copiously. On the day of injection the temperature rose to 39.6°C . at 2.30 P.M., and to 40.3°C at 4.30 P.M. At 5.30 P.M., the patient began to vomit, and at 6 P.M., she became drowsy. At midnight the temperature was 41° , reaching its highest point— 41.5° —at 3 A.M., on December 4. At 9 A.M. on that day the pulse was very small and intermittent, and could not be counted; the respiration was 40. In spite of the free exhibition of stimulants the patient continued to sink, and died at 9.45 P.M., on December 4. The post-mortem examination, which was made by Professor Pommer twelve hours after death, gave striking evidence of the energetic action of the remedy on all the tuberculous foci. There was swelling with redness in the scars and in the neighborhood thereof, and also round the ulcers in the mouth, mucous membrane of the palate and epiglottis; and great swelling of the submaxillary and cervical lymphatic glands, and of those along the trachea, and beneath the bifurcation of that tube and the roots of the lungs. These glands were caseous, and presented in their interior numerous typical tuberculous foci. There were extensive ulcerated areas in the large and small intestine. In both lungs there were numerous disseminated patches of pneumonic infiltration with cedema round about; there was also great cedema of the brain and spinal cord; acute swelling of the spleen, which was 14 centimetres in length, 9½ in breadth, and 4½ to 5 in thickness; and slight parenchymatous swelling of the liver and kidneys. There were capillary hæmorrhages in the pleura, the parietal layer of the pericardium, the thymus, and in several parts of the spinal cord. Among the chronic changes found in the body in addition to the lesions of lupus and tuberculous bronchitis there was callous atrophy of the superficial parts of the apices of both lungs; in these spots there was no sign of reaction. There was also slight stenosis of the left ostium atrio-ventricular, eccentric hypertrophy of the right side of the heart, and hæmorrhagic pachymeningitis. There was neither stenosis nor cedema of the larynx, and there were no tuberculous formations in the lungs.—*British Medical Journal*.

Medicine.

VAUGHAN ON THE CHEMICAL STUDY OF THE SUMMER DIARRHOEAS OF INFANCY.—The author has long maintained that the microorganisms which produce the catarrhal or mucous diarrhoeas of infancy are merely putrefactive, or saprophytic, in character, and that they prove harmful by forming chemical poisons. Booker Escherich, and other able bacteriologists, have made a careful study of the bacteria found in the intestines and stools in these diseases, and all agree that no specific organism is found. From a study of the researches of others, and from his own investigations, Vaughan draws conclusions which he formulates in the following propositions: (1) There are many germs, any one of which, when introduced into the intestines of the infant, under certain favorable conditions, may produce diarrhoea. (2) Many of these germs are probably, truly, saprophytic. (3) The only digestive secretion which is known to have any decided germicidal effect is the gastric juice; therefore, if the secretion be impaired, there is at least the possibility that the living germ will pass on to the intestine, will there multiply, and will, if it be capable of so doing, elaborate a chemical poison which may be absorbed. The chief reason why the breast-fed child has a better chance for life than the one fed upon cow's milk, lies in the fact that the former gets its food germ free; but a second reason is to be found in the larger amount of acid required to neutralize the cow's milk, as has been pointed out by Escherich. The gastric juice is the physiological guard against infection by way of the intestines. (4) Any germ which is capable of growing and producing an absorbable poison in the intestine is a pathogenic germ. (5) The proper classification of germs, in regard to their relation to disease, cannot be made from their morphology alone, but must depend largely on the products of their growth. If these deductions be true, we will try to avoid the introduction into the alimentary canal, not only of the so-called specific pathogenic germs, but of all toxicogenic microorganisms.—*London Med. Recorder*.

TREATMENT OF GONORRHOEA IN THE FEMALE.—M. SCHMITT (*Revue méd. de l'Est*) uses the following method in combatting gonorrhoea in the female: rest in bed and cauterization of erosions with solution 20 per cent. of nitrate of silver. Abscesses of the vulvo-vaginal glands, if present should be freely incised. Injections once or twice each day of at least two litres of a 1:10,000 solution of corrosive sublimate; this is to be followed by an injection of the biniodide of mercury (1:4000) with the hips somewhat elevated. This last injection should be retained for a few minutes and the vagina then packed with cotton saturated with iodoform and glycerine, in the beginning of the affection, and later by a tampon

saturated with tannin. Under this management the inflammation commonly subsides in from ten to fifteen days. When the urethra is affected nitrate of silver may be employed with advantage.

HYPERTROPHY OF ONE HALF OF THE FACE.—KIWALL (*Fortschr. d. Med.*) describes an exceedingly interesting case of this rare condition, occurring in an eighteen year old girl. The trouble had existed from birth, soon after which a peculiar fullness of the right side of the face was noted, which in time increased. At the time she came under observation the enlargement extended from the forehead of the affected side to the throat, the tongue was also hypertrophied upon the right side. The bones as well as the soft parts were involved. A portion of the upper lip excised for microscopic examination showed that the hyperplasia affected only the connective and adipose tissues, while the muscular fibres appeared atrophic.

Surgery.

ISCHIAS SCHOLIOTICA.—LAUENSTEIN, of Hamburg (*Centralblatt für Chirurgie*) cites from a Swedish author the case of a man who had a severe sciatica on the left side. In consequence a scoliosis developed, with convexity towards the left lumbar portion, and in the dorsal and cervical part of the right side. After improving the sciatica by means of warm baths, electricity, massage and antifebrin, the scoliosis disappeared.

CHRONIC MASTITIS SIMULATING CARCINOMA.—PHOCAS, VERNEUIL, LEDENTU and TILLAUX (*Gaz. des Hôpitaux*) have all observed cases of chronic mastitis in women at the second climacteric, which simulated carcinoma. The swelling of axillary glands, emaciation, weakness and anæmia were all usually present. Phocas recommends the application of carbolic spray for a time in doubtful cases, and has seen cases subside under its use.

CONCUSSION OF THE SPINE.—SMAUS, of Munich (*Centralblatt für Chirurgie*), has made some experiments on animals to study the pathology of spinal concussion. The animals were struck on the spine with a hammer, and lived from twenty days to eight months. At the autopsy there were found in some circumscribed foci of softening in the spinal cord; in others gliomata were imbedded in the cord, and some of the conducting fibres were destroyed by pressure. These were considered direct traumatic degenerations, because no hæmorrhage, myelitis or other cause was found. The microscopic examination of parts of cord corresponding to the location of the blows showed swelling and degeneration of axis cylinders, and in some cases of the nerve sheaths and connective substance. The striking inconsistency between the clinical history and the microscopic

appearances shows that more nerve fibres are destroyed by concussion than can be found with the microscope to be degenerated.

UNUNITED FRACTURES.—The *Centralblatt für Chirurgie* gives a synopsis of the fractures treated in the Zurich clinic from 1881 to 1888. Of the 489 fractures presented during those years there were sixteen which healed very slowly, and six which gave place to false joints. In addition, eight cases of pseudarthrosis came to the clinic for treatment. Cases of pseudarthrosis of the olecranon, patella and neck of the femur are not included in the enumeration. In no case was a constitutional cause found for pseudarthrosis among these fourteen cases. The causes were dislocation of diagonal fractures and interposition of muscular tissue, etc. These cases were found to agree with Brun's statistics to the effect that pseudarthrosis is rarer in children than in middle life. Two of these cases were healed by iron nails driven into the connective tissue callus. Four treated by ivory pegs, with one unsuccessful result. Nine were resected, with one unsuccessful result.

Obstetrics and Diseases of Women.

DOUBLE PREGNANCY IN A CASE OF UTERI SEPTUS DUPLEX ET VAGINA DUPLEX.—ALTHEN (*Centralblatt für Gynäkologie*) describes an interesting example of this condition. A woman 31 years of age was delivered of a four and one-half months fetus. On the following day a fetus of like development was born, but the placenta was retained. Althen was sent for on the following day to remove the after birth. Examination showed a complete vaginal septum, that separated two distinct vaginal canals, which extended upwards where they terminated each in a separate cervical canal. By examination a communication could be determined between the cervical cavities. The placentas were removed with difficulty, each from its special uterine cavity. The writer thinks that both vaginal cavities were used in coitus though the right was somewhat smaller. The opening between the cervixes, was he thinks caused by the labor. Unfortunately both fœti had been taken to the cemetery, so he could not determine positively if there was a difference in their ages. The patient says that she menstruated regularly at intervals of two and one-half weeks, alternately 2 to 4, and again six days in length. From this fact the writer concludes that there was an alternation in this function by both uteri.

HÆMOPHILIA AT THE MENSTRUAL PERIOD.—DR. C. TOWNSEND (*Boston Med. and Surgical Journal*, November 26) had recently under his care a healthy, well developed and intelligent girl of thirteen. Some of her family were "bleeders." When an infant, the slightest bruise caused con-

siderable subcutaneous effusion of blood. She bled freely when a little child when cut, or when bitten by insects. Epistaxis was frequent, but ceased after the safe and successful removal of mucous polypi. The joints never became swollen. A "show" appeared at thirteen, and three napkins were stained two weeks later. A week later serious menorrhagia set in, with blanching and faintness. Restlessness, nausea, vomiting and intense thirst, with rise of temperature occurred; as she tossed in bed ecchymoses formed on the shoulders and elbows. As the patient became dangerously exhausted and as the vomiting continued, an enema (one raw egg with three ounces of peptonized milk) was given every three hours. Milk and lime water was administered when the vomiting ceased, and by the end of the week she took beef tea and milk as well as the enemata. The thirst did not diminish until the fifth day of treatment. A tampon, inserted when the flooding was severe, was removed three days later; a slight discharge continued for nearly a week. At the end of ten days the girl was fairly well. It is not stated whether the troubles recurred at succeeding periods. Osler has already noted that in female members of hæmophilic families neither menstruation nor parturition is specially dangerous, and Dr. Townsend notes that other authorities are of the same opinion, according to their own experience.—*Brit. Med. Jour.*

ANTISEPTICS FOR MIDWIVES.—MM. BOURGOIN, BRONARDEL, GUÉNIOT, NOCARD, TARNIER and BUDIN, a committee, have reported to the Minister of the Interior, (extr. du *Bull. de l'Académie de Méd.*) the following disinfection methods for midwives: The hands of the midwife, and genitals of the patient should be cleansed by a mixture of corrosive sublimate 0.25, tartaric acid 1.0, bordeaux red 0.001; on the package should be printed "Sublimate 1.25 for a liter of water, poisonous." Metal instruments should be sterilized by boiling. Sublimate vaseline 1:1000 is also allowed. For simplicity in the disinfection regulations carbolic acid is omitted.

ABSORBING POWER OF UTERUS AND VAGINA.—DR. L. LANDAU (*Berlin. klin. Wochenschr.*, November 10th, 1890) has found from experience that the vaginal mucous membrane has but a feeble absorbing power, whilst the uterine mucous membrane possesses that power to a very high degree. This fact is of extreme importance in gynecology, as strongly medicated tampons may fail to act if inserted into the vagina, whilst if passed into the uterus they may set up grave complication. The vaginal mucous membrane is really skin, and becomes true dry skin in cases of prolapse. The free surface of the cervix has

hardly any power of absorption. Dr. Landau demonstrates from cases how different it is with the endometrium. After the introduction of a solid to per cent. preparation of resorcin into a uterus, severe and long standing uterine colic was set up. The introduction of a 1 per cent. cocaine compound caused the pains to cease. The cocaine was absorbed and by paralyzing the sensory nerves it produced anæsthesia.—*Brit. Med. Jour.*

Bacteriology.

SCHOLL ON INVESTIGATIONS INTO CHOLERA-TOXINES.—The conclusions of the author's experiments, made in the Hygienic Institution of the (German) University of Prague, are as follows: "The toxic peptone which I have produced from genuine albumen, after its destruction by anaërobiosis, is quite distinct from Petri's toxo peptone (formed by aërobiosis), because the latter is not destroyed by boiling, while mine is rendered inert. My choleraicpepto-toxine shows far more poisonous and characteristic properties than the toxins of Brieger and Petri formed by aërobiosis in peptone solutions, for the toxine which I procured (by the cultivation of cholera bacilli) from a single egg was sufficient to kill ten guinea-pigs in ten minutes with acute paralytic symptoms. The assertion of Hueppe and Wood, that more and stronger toxins are formed by cholera bacilli by anaërobiosis than by aërobiosis, is fully confirmed by my experiments, which negative the opposite assertions of Petri."—*London Medical Recorder.*

OPHTHALMIA IN A PUERPERAL WOMAN, CAUSED BY AN EMBOLUS CONTAINING STREPTOCOCCI.—The *Zeitschrift für Geburtshilfe und Gynäkologie* describes the case of a woman, who, a few hours after confinement had a high fever, pain and photophobia in the left eye. On the third day thereafter there was conjunctival and ciliary injection, chemosis, opacity of the cornea and vitreous. The anterior chamber was deepened, the iris discolored and loosened from its attachment and the lens luxated. On this day the patient could still discern light, but on the fourth day total blindness supervened in this eye. On the sixth day the patient died of pyæmia and the eye was removed for microscopic examination. The fact that the retina was found destroyed with the exception of two small islets, that the central artery and vein in the papilla, the vessels of the iris, the ciliary body and sclera were filled with streptococci, led to the conclusion that the streptococci came from emboli; and as there were no appearances of inflammation in the heart or on its valves it was inferred that the streptococci came by metastasis direct from the genitals. Suppuration started in the retina which it destroyed; then the vitreous was fluidified, the lens sank backward, its capsule became eroded, pus entered and filled the capsule.

No. 68 WABASH AVE.,
CHICAGO, ILLINOIS

All members of the Association should send their Annual Dues to the *Treasurer*, Richard J. Dunglison, M.D., Lock Box 1274, Philadelphia, Pa.

LONDON OFFICE, 57 AND 59 LUDGATE HILL.

SATURDAY, JANUARY 31, 1891.

CEREBRAL SURGERY.

In no department of the healing art has there been a more surprising—it may fairly be said, revolutionary change in the last decade than in the surgery of the central nervous system. Two circumstances have concurred to bring about this result. On the one hand, the precision of diagnosis has been vastly increased by the discoveries in cerebral localization inaugurated by FRITSCH and HIRTZ, and amplified by so many investigators, experimental and clinical, that an enumeration of them would be either invidious or tedious. On the other hand, improvements in surgical technique, which have their scientific basis in PASTEUR's discoveries of the relation of microorganisms to fermentation and putrefaction, and LISTER's application of the facts to the infective processes in wounds, have almost abolished the risks, in competent hands, of the secondary troubles which formerly constituted the chief peril of operations in which the cranium was opened. As MR. TAIT has said that he would as soon put his fingers into the peritoneum as into his pocket, so MR. VICTOR HORSLEY, judging from a paper read by him at the Berlin Medical Congress, would probably have no more hesitation in putting his fingers inside the cranium than into his hat. Among the rather startling proposals that he makes are, trephining in cases of obstinate headache, referred to the bone, and incurable by means of drugs; in all cases of cerebral tumor, syphilitic and malignant as well as benign, and whether accessible or not, as he

claims that the operation by diminishing the intracranial pressure, relieves pain, and prolongs life; operation for focal epilepsy, by excision of the portion of the cortex that is found, by electrical stimulation, to be the starting point of the spasm; the same operation in athetosis; and, perhaps the most likely of all to provoke averse criticism, ligation of the common carotid in all cases of cerebral hemorrhages seen in the early stage, when the flow of blood may be presumed not to have ceased. With regard to this last proposition, it was objected, in the discussion that followed the reading of the paper, that the diagnosis of cerebral hemorrhage at that stage is not a very easy matter. The ligature would not be likely to work well in cases of thrombosis or embolism.

Operations for cerebral tumor have hitherto only been proposed in cases in which there was thought to be some hope of removing the growth, and the results can hardly be said to be of a character to excite much enthusiasm, as MR. HORSLEY himself reports four deaths from shock out of eight operations. In this aspect of the subject, a paper recently published by OPPENHEIM, in *Archiv für Psychiatric*, is of interest. Out of twenty-one cases of cerebral tumor in which autopsies were made, he concluded that five were unsuited for operation on account of multiplicity or malignancy, seven on account of the situation of the growths, six on account of the absence of localizing symptoms, and one on account of the syphilitic nature of the tumor, and one on account of its size, leaving only three in which operation would have held out a reasonable hope of success. HORSLEY is of the opinion that gummatas should be excised, as he believes the iodide treatment to be only palliative, never curative. If as much relief of symptoms as he hopes for can be obtained by trephining in cases in which the tumor cannot be removed, the operation would seem to be justifiable, but, taking the most favorable view of it, we can hardly expect that it will rival ovariectomy in its results.

The above propositions will probably strike most of our readers as sufficiently venturesome, but they by no means satisfy the ambition of some operators. Trephining has been practiced for general paresis by CRIPPS, in England, in two cases, both of which were said, at the time they were reported, to show decided improvement subsequently

to the operation, and by WAGNER in this country, with some apparent temporary relief, the patient dying about two months after the operation. In view of the desperate nature of the disease, there is probably no serious objection to such a procedure, however little prospect there may seem to be of permanent benefit. The case seems rather different with the operations of which BURKHARDT gave an account at the Berlin Congress. He excised portions of the brain from the regions that he judged to be specially affected in cases of insanity without gross lesion. For hallucinations of hearing, for instance, he removed portions of the first temporal and second frontal convolutions, and in a case of excited dementia of syphilitic origin, portions of the frontal lobes. Aphasia and word deafness followed in some of his cases, and one patient out of six on whom he operated, died, apparently as the result of the operation.

DR. HOLMES characterizes those of our fellow-citizens commonly known as "cranks" as the possessors of squinting brains. At the present rate, we may perhaps expect that operations for cerebral strabismus will become as common as for squint-eye. Few of us, probably, can pretend to an absolutely symmetrical mental organization, and if harmony could be brought about by a little judicious paring of our brains, here and there, it would be a consummation devoutly to be wished. Whether, in case the difficulties of operative procedure can be overcome, it would be desirable, in any cases, to extirpate the cerebral hemispheres completely, need not be decided at present. There are some persons who could, apparently, be little injured by such an operation.

PEDAGOGY IN MEDICINE.

Most of us remember but little of our teachers. At the best only a few names loom up with a back-ground of gratitude, and these represent those whose hearts were in their work. Excluding the many who taught in a perfunctory way as the means to some end, the idea-imparters may be counted upon the fingers of a hand. The few excluded from the category are they who sought to make us equal to themselves, not so much in extent of knowledge as in the sources from which it was derived. They are those who taught us to classify and aimed not to merely present a mass of verbiage in a well-padded discourse to kill

time. How can we deify the conventional lecturer whose eyes seldom leave the manuscript, which for years has done duty with a perseverance worthy of a better cause?

Now that didactic teaching appears to be threatened with extinction and the art of the pure clinician has come into favor, what have our teachers to present in return for the prerequisites which have been gained after so much distress to the aching purse? What are the advantages offered in return for so much sacrifice? The student, aware of his rights in the premises, and vacillating between ambition and necessity, replies but little if anything. Too often is he conscious that he receives only a modicum in jargon or dogmatism in return for his confidence, and that his diploma is to be flanked by crude theories and mal-assimilated facts. Much that he may have learned he finds that he cannot make practical, and that the mannerisms of his preceptors are inapplicable beyond the class room. The aphorisms, which have been dimmed into his ears he is fain to discard because the amplitude of argument with which they were enforced was grounded in error. And so he goes on until his revisions make a new text, and for the matter of that a new sermon.

Are the teachers of the day impressed with a sense of their responsibilities? We fear not. We hold that only the few appreciate the importance of their mission, and that of these few only a very small minority walk with their pupils. And what of the majority? Do they not satisfy themselves with wasted words and crude principles? Why we ask also may not every branch of our science be made interesting? We claim that it is beyond doubt possible—that demonstration, illustration, simile, anecdote and apothegm may be pressed into service. Further than all this we are ready to endorse what has so often been said, that teaching is quite enough of a specialty to attract the best of minds. But then we also must in duty offer the corollary that every instructor should make his subject presentable, and be made aware that he cannot afford to deceive the yearners after truth who pit the brevity of life against the gravity of the work before them.

Above all else, the student should be taught courage. With the responsibilities that are to confront him, he can hardly be expected to be

armed cap-a-pie and yet be unready for the fight. He is entitled to the hope of glory, which is to be gained certainly not without an effort, and even in spite of a studied dampening of all youthful ardor. This duty of stimulation can belong to none others than the college faculties with which our country abounds. A few endowments scattered among the more worthy of the institutions, might mend matters somewhat, but as long as there is so much fighting of the wolf at the door, we fear that pessimistic views will prevail. Still there is much room for hope, and to the future we look for a more complete solution of the problem.

BACTERIOLOGICAL RESEARCHES.

It is not now possible to estimate the enormous impulse given to experimental pathology by KOCH's discovery. We may doubt that a cure for tuberculosis has been discovered, indeed we may affirm that it is only a remedy or mode of treatment. But if it has not been discovered it will be sooner or later. KOCH is said to have used the words "ich habe es gefunden" in making the preliminary announcement to his medical friends. Not for years had he doubted but that the cure was ever awaiting upon discovery.

The zymotic origin of most of the epidemic and infectious diseases has been accepted by many for years, indeed the probabilities were so strongly in favor of it that the views were accepted long before the demonstrations. When they came they were adopted almost as a matter of course, by some, and denied by others. This is but a repetition of the history of similar discoveries, for it is now apparent that certain diseases, notably anthrax and tuberculosis, are as conclusively proven to be due to microbic infection as that the law of gravity acts when an object falls to the earth.

Another proposition, while not as conclusively proven, is still rendered highly probable, that is the bacilli are perhaps harmless in themselves, only exceptionally do they act in a mechanical way in obstructing vessels, or interfering with the nutrition of tissues. Their chief disturbing influence seems to be due to substances, toxins, ptomaines, or tox-albumens formed by them, which exert a local destructive action, or by reason of dissemination through the blood cause a general toxæmia. Several of these bodies have

been isolated from pure cultures of various pathogenic bacilli, now it is apparent that these substances circulate in greater or less abundance in the blood and doubtless also appear in the urine. EHRLICH's test, or the so-called diazo-reaction, demonstrates that in the urine of a typhoid fever patient there is a substance present which is not found in healthy urine. Unfortunately the reaction is also found in cases of phthisis and septicæmia. Is it not probable that identical substances are not present but they all give the same reaction, just as some reagents will precipitate several elements? What we now need is a careful study of these products and if possible their recognition by simple chemical tests so that in the future all that will be necessary is to determine, by examining the urine or other fluids, what ptomaine is present and then apply the proper antidote. All this is beautifully simple, but it is probable that it will be some months before it will be an accomplished fact. Still in the light of the discoveries of the last few years it seems well within the bounds of the possible.

One lesson it ought to teach and that is the boundless reach of science. In medicine more facts have been learned since 1850 than were previously known, and yet each discovery only teaches us how much more there is to be learned. While the bacteriologist now seems to be in advance, he but points the way for the chemist and pathologist.

EDITORIAL NOTES.

AN OLD ADAGE REGARDING TYPHOID FEVER.—In an article by Dr. S. C. Benedict of Athens, in the Georgia State "Transactions" for 1890, just published, the writer calls to mind a long forgotten adage of that "sage of Baltimore," Dr. N. R. Smith, that in the treatment of typhoid fever there were mainly needed three things, "a vial of laudanum, a bottle of turpentine and a hog-head of buttermilk." This is a *prop* to the note printed on page 907 of our last volume, where we quoted the recommendation of Dr. H. C. Wood in favor of a return to the turpentine treatment of fifty years ago.

A RUSSIAN ANTHROPOLOGICAL PRIZE.—Dr. Parnowski, a female physician of Russia, has recently been awarded a gold medal, as a prize, for

her essay on the anthropology of prostitutes and female thieves. The award was made by the Moscow Society of the Friends of Natural Science, Anthropology and Ethnography.

KINGS COUNTY MEDICAL ASSOCIATION.—The anniversary meeting of this society was held at Brooklyn, N. Y., January 13, when the following officers were elected for the ensuing year: John D. Rushmore, president; A. R. Paine, vice-president; John R. Vanderveer, treasurer; J. C. Bierwirth, Secretary; H. B. Reed, corresponding secretary and S. H. Benton, member of executive committee.

A NEW SECRETARY FOR THE SECTION OF STATE MEDICINE.—Dr. Benjamin Lee has been appointed Secretary of the Section of State Medicine of the American Medical Association in lieu of Dr. Bascum, who has resigned on account of ill health. Dr. Lee requests that all physicians desiring to participate in its discussions or to present papers should forward him their names as early as possible. All papers should be in his hands not later than April 15th, 1891. Dr. Lee's address is 1532 Pine St., Philadelphia, Pa.

FOR A WOMAN'S SCIENTIFIC COLLEGE.—Dr. Henry Muirhead, recently president of the Glasgow Philosophical Society, has bequeathed the sum of \$125,000 for the erection and endowment of a scientific college which shall be devoted entirely to the instruction of women in surgery, dentistry, electricity and chemistry.

THE CHICAGO POLICLINIC.—Experimental work with Koch's lymph has been in progress for two weeks or more at this institution. A number of typical cases of tuberculosis have been selected, and the results as they shall be reached will be under the observation of men alike competent and reliable for the rendering of just conclusions. It is yet too soon to record results; when ample trials shall have been made, our readers will be interested to know the measure of their success.

A MODIFIED PROGRAMME.—In the absence of Dr. Norman Bridge, the Faculty of the Chicago Post Graduate Medical School invited Professor Gibbs, of the Michigan University, Ann Arbor, Mich., and Professor E. L. Shurley, of the Detroit College of Medicine, to occupy the evening assigned to Dr. Bridge in the regular

course of lectures, and to give their views of the pathology and treatment of phthisis pulmonalis.

It will be remembered that Dr. Gibbs ignores the bacillus as the primal cause of phthisis, and that Dr. Shurley is conducting a series of experiments upon animals, by means of inhalation of chlorine gas in the presence of the vapor of chloride of sodium, the results of which he is as yet not prepared to state.

An invitation to the medical profession of Chicago to listen to the addresses of these gentlemen met with a prompt and general response, and a large audience of the leading physicians of Chicago was in attendance. Such reports as we were able to secure of their impromptu addresses will be given in a later issue of THE JOURNAL.

THE MARITIME MEDICAL ASSOCIATION.—This is the fitting name provisionally adopted for a new Canadian medical society which will organize in July, 1891, at St. John. Three great seaboard provinces have united for its formation in the hope of creating a powerful body in influencing medical legislation and strengthening the profession within and without. According to the *Maritime Medical News* the following officers of organization have been chosen: President, Dr. William Bayard of St. John; Vice-President for New Brunswick, Dr. Thomas Walker of St. John; for Nova Scotia, Hon. Dr. D. McN. Parker of Halifax; and for Prince Edward Island, Dr. Richard Johnson of Charlottetown; Secretary and Treasurer, Dr. Arthur Morrow of Halifax; Local Committee, Drs. Bruce, Daniel, Christie and Hetherington. The time and place of meeting corresponds with the annual session of the New Brunswick Medical Society, by which the initiative of this movement was made in 1883. The older provincial societies will not be interfered with by the new Association.

THE MARITIME MEDICAL NEWS.—This bright little journal is launching forth, with the beginning of its third volume, in the form of a monthly. Its able editor is Dr. Arthur Morrow, Argyle street, Halifax, N. S.

GERMAN CONGRESS OF INTERNAL MEDICINE.—The tenth Congress of Internal Medicine will be held, April 6 to 9, at Wiesbaden, under the presidency of Dr. Leyden of Berlin. Fürbringer of Berlin, with Naunyn of Strasburg, will introduce the clinical relations of hepatic calculus;

Fraenkel and Vierordt will treat of angina pectoris, while addresses will be presented by Schott and Kahler.

MEDICAL ITEMS.

EARLY MARRIAGES IN INDIA.—The Government of India has decided to legislate on the subject of the age of consent by a simple amendment to the penal code, substituting the age of twelve for that of ten. It had been wisely determined to couple the announcement with the assurance that no interference with social or religious customs affecting early marriage is contemplated, a course which it may be hoped will satisfy those who saw in the suggested reform a covert attack on ancient customs.

THE KOCH TREATMENT IN LEPROSY.—The condition of the three lepers recently inoculated at Madrid with Dr. Koch's liquid in the Hospital of St. Jean de Dieu is stated to be satisfactory.

PROFESSOR VIRCHOW. lately elected by acclamation an honorary member of the Regia Accademia Medica di Roma, has just acknowledged the compliment paid to him in a letter to the president, Dr. Guido Baccelli—"I am proud and happy to find myself so united by a new tie to Italy—proud to be affiliated in Rome to a body so learned and so distinguished, happy to feel myself among new friends."

CHICAGO AS A PLACE FOR DOCTORS.—The secretary of the Illinois State Board of Health, in his recent quarterly report, states that there has never been such a rush of medical men to Chicago as during the past three months. More than two-thirds of the certificates issued were to physicians who wished to practice in Chicago. And never before in the same length of time have so many professional frauds attempted to obtain a foothold in Chicago. It is evident that the increase of population, and especially the coming World's Fair, are the attractions. Eleven applicants were refused licenses because they had diplomas from schools not in good standing, because their professional records had been tarnished elsewhere, or because they could not comply with the requirements of the Board. The anxiety to settle in Chicago is also manifest in the incorporation of so-called medical companies, medical associations, and dispensaries, thus taking advantage of the lax laws and attempting to evade the Medical

Practice Act. New York, not having the World's Fair, will take pleasure in sending on her medical men that will not be missed here.—*Medical Record.*

PROPOSED MEDICAL LEGISLATION IN PENNSYLVANIA. The present registration law of Pennsylvania is said to be almost a total failure. According to the *Times and Register* another attempt will be made during the coming session of the Pennsylvania legislature to procure the passage of an act creating a Board of Medical Examiners. The proposed bill places the appointment of members entirely in the hands of the governor; the only restrictions to this choice being those relating to legality and date of graduation, and freedom from alliances with medical colleges. A new clause provides that no two of the nine examiners shall be residents in the same county. This opens the field to the country members, and cuts Philadelphia, with her 2,000 physicians out of 8,000 in the State, down to a single representative.—*Med. Record.*

MRS. FOGG'S BEQUESTS.—By the will of Mrs. Fogg, the widow of a rich merchant in the China trade, the New York Hospital receives \$20,000, the Metropolitan Hospital \$10,000, and the Children's Aid Society \$55,000; and among the many other institutions benefited are the New York Diet Kitchen and the Training School for Nurses of Bellevue Hospital. The largest bequest is to Harvard University, namely, \$200,000 for the erection of an art museum. In addition, Mrs. Fogg bequeaths her late husband's Japanese and East India collection, valued at \$100,000, and the sum of \$20,000, to be applied to the current expenses of the museum and the purchase of works of art.—*Boston Med. and Surg. Journal.*

THE seventh annual meeting of the Fifth District Branch of the N. Y. State Medical Association will be held in Brooklyn on Tuesday May 26th, 1891. All Fellows desiring to read papers will please notify the Secretary, E. H. Squibb, M.D., P. O. Box 94, Brooklyn.

The Journal of Inebriety says: "The physician of all others should be the last one to use spirits in moderation or excess. The use of alcohol as a beverage, is direct evidence of ignorance of the teachings of modern science, and failure to keep up with the growth of medical advance."

TOPICS OF THE WEEK.

FERDINAND COHN AND ROBERT KOCH.

At a time when all the world is talking or has just been talking about Robert Koch, the following word portrait of him by a distinguished man of science who has known him for many years is likely to interest many. It is from the January number of the *Deutsche Revue*, and its author is the famous botanist, Professor Ferdinand Cohn, of Breslau. "When I made Koch's acquaintance," he writes, "he was already the great investigator whom all the world now knows and admires. On the 22d of April, 1875, I received a letter from the district physician, Dr. Robert Koch, of Wollstein, in the district of Bomst, in the grand-duchy of Posen, asking whether I would allow him to visit me in Breslau, and perform before my eyes the chief experiments relating to anthrax and its characteristic bacilli, the history of the development of which he believed he had now discovered after prolonged investigations, and with it the etiology of that destructive disease. I had been myself engaged for years past with bacteriological investigations, and had consequently often received announcements from dilettanti of their alleged discoveries in that field, which was then being cultivated with but little precision; the expectations, therefore, which that letter from an utterly unknown physician in a Polish country town inspired in me, were of the smallest. I of course wrote, however, that I should be very glad if Herr Koch would visit me and show me his things ("seine Sachen"). Koch came to my institute on April 30, and I can truly boast that in the first hour of our intercourse I recognized in him an unequalled master of scientific investigation; his method, proceeding with rigid consistency from step to step, the elegance and certainty of his experiments, the classic clearness of his statements, were all as perfect in his first, then just completed, work on anthrax as in all his later researches. For Koch's works are distinguished from those of most investigators by the circumstance that he does not publish them till they are finished to the last point. Others cart up stones to be used in the building up of science, or draw a new plan or add a new wing, a new story, a new roof, but they finish only the brickwork, and leave it to others to complete the building and make it habitable. Koch, on the other hand, does not let his scientific fabrics leave his hands till he has made them completely fit in all their details, as well as in the main, for the use of others, who have then nothing more to do than to add this or the other little furnishing. All Koch's works have been so complete in form and contents that nothing remained for those that followed but to confirm them, for it was not possible to add anything essential. Such were the first work of 1875 on anthrax, that on wound infection, the numerous treatises in the communications of the Imperial Office of Health, the magnificent researches on the tubercle and cholera bacilli, and such beyond doubt his latest discovery will prove. On his first visit in May, 1875, Koch stayed only a short time in Breslau, and I availed myself of the opportunity to make my Breslau colleagues personally acquainted with him

and his researches. I then remained for years in occasional correspondence with him. His letters generally filled several sheets. He repeated his visits to Breslau too; and when the place of a medical expert in the law-courts there fell vacant in the summer of 1879, we succeeded in getting him appointed to it, with the prospect of an extraordinary professorship in the University. But already in January, 1879, the medical faculty of the University of Berlin had of its own accord proposed to the Minister Koch's appointment to an extraordinary professorship, and the establishment of an institute for him. Some papers say that Koch wished to establish himself as a private lecturer in Breslau, but was refused permission. That is utterly untrue.

The proposal of the Breslau faculty had been made without Koch's knowledge. His work as a medical expert in the law courts could not satisfy him either scientifically or pecuniarily, and he returned, after a few months, to Wollstein, where his place as district physician had been kept open for him. That he did not remain there long, but was called to the newly founded Imperial Office of Health in Berlin in 1880, did great honor to the German Government, and was of great advantage to science—namely, to all mankind. But if you ask me for reminiscences of conversation with Koch, I can only say that in personal intercourse Koch makes the same overpowering impression as in his writings by the clearness, depth and novelty of his thoughts, only that this impression is greatly enhanced by the simplicity and amiability of his manners, the look of his deep-set eyes, his fine smile, and the euphony of his voice. In conversation with Koch, one is often positively dazzled by occasional remarks or short questions, indicating still unknown researches that he has been working at for years, and revealing new scientific horizons. But of details of the conversation which I and my then assistant, Dr. Eidam, had with Koch, and which sometimes lasted deep into the night, I have no remembrance."—Correspondence of *The Lancet*.

DR. HENRY J. BIGELOW AND THE DISCOVERY OF ANÆSTHESIA.

In a speech delivered at a memorial meeting of the Boston Society for Medical Improvement, on the occasion of the death of Dr. Henry J. Bigelow, Dr. O. W. Holmes said:

Dr. Bigelow sometimes paid me the compliment of asking my opinion of, and my criticism upon, an essay or a lecture he was about to read or publish. On an evening of December, 1846, he called upon me with a paper which he proposed reading the next evening at the regular meeting of the American Academy of Arts and Sciences. He began by telling me that a great discovery had just been made and practically demonstrated in the operating theatre of the Massachusetts General Hospital. He proceeded to read the paper, which was the first formal presentation to the world of the successful use of artificially produced anæsthesia in a capital operation. He had the sagacity to see the far-reaching prospects of the new discovery, the courage as well as the shrewdness to support the claims of the adventurous dentist's startling, at first

almost incredible, announcement. Every possible effort was made to dislodge the infant anesthesia from its cradle in the Massachusetts Hospital, but there remains the fact that all over the wide world patients were shrieking under the surgeon's knife and saw—operator and victim alike ignorant of the relief in store for them, at the very time when Dr. Bigelow was unfolding in my library the first paper ever written on the subject, and saying to me as he did so, that within a fortnight the news of the discovery would be all over Europe. From the first, Dr. Bigelow was the steady, unflinching advocate of ether as the safest of the anesthetics, and his views, though not universally accepted, have had a very wide and lasting influence.—*Northwestern Lancet*.

MEDICAL EDUCATION IN BELGIUM.

The *Scalpel* is endeavoring to impress upon the more highly gifted of the young Belgian medical graduates the desirability of their forming, as they have the right to do, extra classes for the instruction of students and legally, but not practically, qualified men; also for older practitioners who wish to keep abreast of the latest developments of science. The example of Germany is quoted, where it is admitted that the course of study is much better than in Belgium, no one being allowed to practice without having undergone a "very severe" State examination, but where, notwithstanding, numbers of *privat-docenten* open courses on almost every conceivable subject, to which students and practitioners flock in order to qualify themselves still better for practice. The same kind of system obtains in Paris, where the *agrégés* hold numerous and well-attended classes. In Belgium, however, "owing to the competition in higher education, our Universities, in order to attract students, have only to show themselves more lenient and less severe than their rivals, and they will surpass all others in their student's roll."—*Lancet*.

HEALTH AND LONGEVITY OF ABSTAINERS

At the last meeting of the British Medical Temperance Association, a paper was read by Dr. C. R. Drysdale, in reply to some doubts as to the superior health and longevity of total abstinents from alcohol. He referred to the report of the Collective Investigation Committee of the British Medical Association on alcoholic habits and mortality, which is still being used extensively by opponents of total abstinence in spite of the disclaimer of Dr. Owen and the explanations given by others. After quoting the statistics by Dr. Ogle, Mr. Nelson and others, which showed the very high mortality of persons engaged in the liquor traffic, he instanced the results of the United Kingdom Temperance and General Provident Institution, which showed that, from 1866 to 1889, 6,804 deaths, and claims for £1,470,147, were expected in the General Section (non-abstainers), and that 6,645 deaths occurred=96 per cent., and £1,428,671 were claimed in the Temperance Section (total abstinents), 4,542 deaths, and claims for £983,307 were expected, and 3,195 occurred=70 per cent., and £664,832 were claimed, showing an immense difference in favor of the total abstinents.

The Sceptre Life Association was also instanced, as having two sections, and in this office in the General Section during the last six years 700 deaths were expected, and 434 occurred=79 per cent.; in the Temperance Section 249 deaths were expected, and 131 occurred, or 57 per cent. At the same time the average age of those dying in the General Section was 51.3 years, and in the Temperance Section 44.2 years—a result, as was explained in the discussion—due to the fact that the average age of abstainers is at present much below that of all males. He also noted the fact that several accident insurance offices reduce the premium to abstainers, the secretary of one having explained this as not so much due to the number of accidents being slightly less, but to the fact that abstainers recover more quickly. He also compared the rates of mortality in the Foresters and Rechabites, showing a constant difference in favor of the latter at every age. The days of sickness per member were for the Rechabites 6.16, for the London Grand Division of the Sons of Temperance 5.5, and for the Oddfellows 10.5 days.—*Brit. Med. Jour.*

MEDICAL SCHOOLS MUST BE ENDOWED

The following timely words are the conclusion of an editorial in the *Cincinnati Lancet Clinic*, January 3:

The time is rapidly slipping by when medical schools and colleges can be carried on and conducted solely by the enterprise of a faculty made up mainly of hard-worked and often poorly supported physicians. Medical schools must be endowed in order to most efficiently carry on their work. The best teachers are often the most impecunious of men. Their thoughts are not given to the making of money, however necessary this may be, but in other channels—they may be doing a much greater and a much better work for the world, than the man who writes his signature as president of a bank or railroad.

There are men, and women too, whose lives have been prolonged and made more comfortable through the skillful application of the art and science of medicine. The presented bill of the attending physician may have been promptly paid, but a debt to science remains unsettled; a science that has made it possible for the attending physician to afford the longed for, the hoped for relief from pain and suffering. Those who are possessed of large means should remember this, and remember that they are but stewards, and that in a broad sense they are their brother's keeper. They are responsible for the well-being and refinement of all the people. They are likewise to be rewarded in unmeasured gratitude for the good deeds they may perform in efforts made to elevate those less fortunate than themselves. Free education is the chief bulwark of our free republic. Free education lessens crime and makes the impossible, possible.

It is eminently just, right and proper, that the entire people should contribute according to their means for the common school education of every child; while there is just as great a moral obligation on the part of the wealthy to contribute of their super-abundance towards the higher educational schools. Among these the medical schools are among the most important, and their claims should be set forth by those who know them best.

Physicians should present this subject to their clients at every opportunity.

PRACTICAL NOTES.

SULPHONAL IN DIABETES.

Dr. Casarelli, of Pisa, mentions the favorable action of sulphonal in diabetes (*Lancet*). The drug diminishes the quantity of sugar in the urine, also reducing the polyuria and the thirst. These results were obtained by doses of from 5 to 30 grains per diem, but not to so marked a degree as with doses of 45 grains continued for several days. The 30 grain doses could be administered for some time without any ill effects; but although the 40-grain doses at first caused no disturbance, it was found that, when they were continued for any lengthened period, they caused giddiness and excessive sleepiness, which disappeared when the drug was discontinued.—*Medical Record*.

CHRYSAROBIN IN HÆMORRHOIDS.

A Paris correspondent of the *Pharmaceutical Record*, April 7, 1890, states that extraordinary success has been reported with chrysarobin in the treatment of hæmorrhoids. For the external variety he prescribes the following ointment, to be applied several times daily after a washing in a 1 to 50 solution of phenic acid, or a 1 to 100 solution of creolin: Chrysarobin, 80 ctgr.; iodoform, 30 ctgr.; ext. belladonna, 60 ctgr.; vaseline, 25 gm.; for external use. For internal use, the formula is as follows: Chrysarobin, 8 ctgr.; iodoform, 2 ctgr.; ext. belladonna, 1 ctgr.; cacao butter, 2 gm.; make one suppository. In three or four days pain and hæmorrhage are said to disappear, and it rarely happens that the most obstinate cases are not cured within two or three months.—*College and Clinical Record*.

CREOLIN IN ERYSIPELAS AND ECZEMA.

Dr. Rothe (*Attenburg: Memorabilien*, 9; *Brit. Journ. of Derm.*, November, 1890), has used in the treatment of erysipelas a creolin ointment containing creolin 1.5, cret. præp. axung porc., $\bar{a}\bar{a}$ 15 o, ol. menth. pip. gtt. v. This is spread in the thickness of the blade of a knife over the diseased parts twice or three times a day, a thin layer of cotton wool being applied as a covering. In from twelve to twenty-four hours improvement was always apparent, and the disease was cured in three or four days. The same ointment also did good service in a case of weeping eczema of the face, as also in several cases of eczema in children. A patient suffering from scabies was treated with a thorough washing with soft soap and inunction of this ointment, with such a decided effect, that Dr. Rothe considers creolin to be undoubtedly a specific for the disease.—*British Medical Journal*.

ICHTHYOL IN THE TREATMENT OF GONORRHOEA.

Köster (*Wiener Medizinische Presse*, November 23, 1890) writes enthusiastically of the use of a 1-per cent. solution of ammonium sulph-ichthyolate in gonorrhœa. He has used it in three cases of gonorrhœa in men and in one case of gonorrhœal cystitis in a woman. In the cases of gonorrhœa he employed injections of the solution three times daily. On the second day of treatment the painful micturition and the painful nocturnal erections disappeared. The discharge ceased permanently in from four to twenty days.

In the case of cystitis, in which the symptoms were severe, four and one-half ounces of the solution were injected twice daily for eight days by means of an irrigator, the solution being retained in the bladder for five minutes, and then permitted to escape through the urethra. After the second day of treatment the pus disappeared from the urine and there was no longer severe pain.—*Medical News*.

SOLVENT FOR DIPHTHERITIC MEMBRANE:

- R. Pepsine, 5 jss.
Ac. hydrochlor. dil., \mathfrak{m} j.
Aq. dest.,
Glycerinæ $\bar{a}\bar{a}$ 5 ss. \mathfrak{M} .
Sig. Paint.

—*Canada Lancel*.

BRONCHIAL ASTHMA:

- R. Ammonii iodid., 5 ij.
Extract. grindellæ robust. fluid., f 5 ss.
Extract. glycyrrhizæ fluid., f 5 iv.
Tinct. lobeliæ,
Tinct. belladonnæ, $\bar{a}\bar{a}$ f 5 ij.
Syrup. tolu. q. s. ad f 5 iv. \mathfrak{M} .
Sig. A teaspoonful t. d. Extra dose to be given during a paroxysm.

—*Amer. Journ. of Med. Sciences*.

SOLUTION FOR THE ECZEMA OF DENTITION:

- R. Hydrochlorate of cocaine 2 grains.
Bromide of potassium 15 grains.
Pure glycerin }
Distilled water } of each $\frac{1}{2}$ ounce. \mathfrak{M} .

Rub thoroughly together, and apply to the parts with the soft part of the finger. If insomnia is present, owing to the itching produced by the eruption, a teaspoonful of a syrup made up as follows will be found useful:

- R. Bromide of potassium 7 grains.
Syrup of orange 1 ounce. \mathfrak{M} .

For the cure of the condition, an ointment composed of oxide of zinc, 1 drachm, and vaseline, 3 drachms, may often be employed with advantage.

—*Medical News*.

EXCESSIVE MENSTRUATION.

- R—Ergot dialysat, 5v.
Glycerin, 5v.
Acid salicylic, gr. xxx.
Aqua destillat., f 5 jss. \mathfrak{M} .

Sig. Inject into the rectum once a day a teaspoonful of this mixture, diluted with three teaspoonfuls of water.

SOCIETY PROCEEDINGS.

Allegheny County Medical Society.

Special Meeting, November 18, 1890.

W. S. FOSTER, M.D., PRESIDENT, IN THE CHAIR.

ENORMOUS DROPSY OF THE BELLY.

DR. LANGE: I have a patient here, aged 48 years, who has been sick 18 months. I present him because I believe him to have the largest amount of ascites ever recorded. He has interstitial hepatitis, or cirrhosis of the liver, and was tapped this morning, this being his ninety-ninth tapping, at each of which there has been evacuated from four to six gallons of serum. A year ago he required tapping every two or three days; at the present time we tap him once in five days. Once he went six days. Averaging the evacuation of serum at five gallons at a tapping will give a total of 495 gallons of serum which we have drawn from this man, or twelve and a half barrels, counting forty gallons to the barrel. His general health is moderate. As you see, he does not look very anæmic. He is not very sick. His functions are all fairly well performed. His appetite and digestion are fairly good and he sleeps well. If he could get rid of his dropsy, he would be in comparatively good health. He has no complications. His kidneys are normal; the same is true of his heart, and he has no pachymeningitis. The reason he has a greater amount of ascites than is common in cirrhosis of the liver, is because his collateral circulation is not as good as it usually becomes early in this disease. This lack of development of the collateral circulation is the cause of his greater than ordinary amount of dropsy. The blood in his portal vein being denied admittance to the liver, greatly over distends the mesenteric veins, and this intra-venous pressure is the direct cause of his dropsy. The collateral circulation established is by anastomosis of the mesenteric with the abdominal veins, the coronary vein of the stomach with the veins of Glisson's capsule on the one hand, or with the phrenic veins on the other, the internal hemorrhoidal with the hypogastric, and finally, as pointed out by Baumgarten, enlargement of the not yet obliterated umbilical vein in the ligamentum teres. By all these ways the blood from the portal system reaches the abdominal veins—a direct reverse to the normal, and the greater or lesser perfection of this collateral circulation determines a small or a large ascites. In this case the abdominal veins, and the caput Medusæ, too, are not as large as usual, and as a consequence, the dropsy is so much larger. If this collateral shall improve, his dropsy will become more moderate; if it become perfect, this dropsy will disappear. But we do expect this latter to happen. Dr. Flint reported two cases in which it did happen. But this

is rarely the outcome of this disease. And we do not expect so favorable an ending. We expect, however, that his circulation will improve, and that he will then have a moderate dropsy only, and will have a fair degree of health and perhaps again become a useful member of society.

CASE OF LUMBO-COLOMOTOMY.

DR. LANGE: The other case is of lumbo-colotomy for cancer of the rectum. This lady is 47 years of age. The cancer was removed last April. Its return, however, was very rapid, and necessitated this operation, which is rather rare, forty-seven cases being all I can find recorded. The lady whom I will show you in a few moments passed absolutely nothing through her rectum for a period of seven weeks. She was so tender and distended that peritonitis was suspected. She vomited constantly, could take no nourishment nor drink three weeks before consent to operation could be obtained. It was obvious that she must die or submit. The operation was done 6 weeks ago to day. There was no peritonitis. The only drawback that she has experienced is prolapse of the gut, which she now prevents by this little cushion and bandage. She has grown strong and eats and sleeps well. The operation was done with the observation of all antiseptic precautions—until the opening of the gut. Two double ligatures were passed through the gut before it was opened, and by them it was lifted to the surface of the wound. It was then opened, and so great was the discharge of fecal matter, that the whole wound was soiled. The opening into the gut was 1½ inches long, and the edges were secured to the skin by eight sutures. All the sutures, however, suppurated out, and after ten days there was no union between the gut and the skin. This is not to be expected in this operation. The sutures are only intended to temporarily hold the gut in position until there is union deep in the wound between the muscles and fasciæ, and not the edges, but circumference of the gut. This is here, as you see, perfect, and no danger that the gut may recede exists. I am indebted to Drs. Hamilton and Herron for advice and assistance during the operation.

DR. BUCHANAN: I would ask Dr. Lange whether he took into consideration the advantages of inguinal colotomy, the drawing of the sigmoid flexure of the colon forward, and making an anterior instead of a lumbar incision. This operation would answer as well as the operation which he performed, and it has the great advantage that one is able to make it an antiseptic operation throughout, which he was not able to do in this case. Of course this case turned out as well as could be wished. But by bringing the gut through the abdominal walls and keeping it there until adhesions have taken place before it is opened, he gains a perfect adhesion without dan-

ger of soiling his wound. Then when adhesion has been established, the gut is opened and its contents allowed to escape. It seems to me this is rather a better operation than the lumbar operation, and safer, and the control of the feces is very much better than in the lumbar operation.

DR. LANGE: Answering the doctor, I would say that the operation in front involves opening the peritoneal cavity; the lumbar region does not. Until in the last few years it has not been considered superior to the lumbar operation. This has come, of course, because of antisepsis. The lumbar operation should be absolutely safe, because the probability of opening the peritoneum is just about as great as of entering the peritoneal cavity by puncture of a full bladder. It sometimes happens that in the puncture of a full bladder the peritoneum is opened by the trocar, and the opening of the gut in the lumbar region is on a par with that for danger. There is very little danger. The operation in front, it seems to me, is more dangerous, despite all antisepsis, because of the opening of the peritoneum. I understand Dr. Buchanan to advise waiting some days for adhesion after opening the belly, before opening the gut. There was no time for that in this case. The operation was postponed by the patient as long as it was possible. When it was absolutely necessary to have it performed, with death as an alternative, she consented to it.

DR. ALLYN: At the last meeting Dr. Bane read a paper relating a case of an hysterical child. I have seen a case quite similar. A girl 14 years old, recovering from sickness, complained of her eyes failing her in reading. She was taken to a physician, and finally came under my charge. I put the card the proper distance; she failed to see anything with any clearness. Putting on glasses of different strengths, I reduced the strength to plano. Then she read the card perfectly. Taking the glasses off, she no longer saw anything. Fearing there might be paralysis of the ocular muscles, I tested her for close use. In this case, she saw nothing until glasses were applied and finally reduced to plano, when she read diamond type with perfect ease. I told the mother nothing was the matter practically with the eyes. I told her the girl had hysteria; and since that time she has been taken with hysteria.

DR. LIPPINCOTT: I saw yesterday morning a similar case. Curiously enough, nearly all the cases I have seen have been girls of about 10 years. I do not think they vary more than a year or two either way. This child that I saw could not see, apparently, any letters across the room at all. By putting up the large letters which can be read at 200 feet, she managed to read. The next size she thought she saw dimly. She called M. I. I thought instantly she was shamming, as her answers were not compatible, and I got her confused by giving her a whole battery of

questions and answers at once. She was thrown off her guard and saw the very finest letters. These cases are not very uncommon. I have seen half a dozen. This child yesterday was a type of a pretty large class. Dr. Holland, of Philadelphia, called attention to this a number of years ago. I think the majority of cases are in girls, showing that the trouble is probably hysterical.

DR. T. D. DAVIS: The following cases will illustrate

THE WONDERFUL RECUPERATIVE POWER OF THE HUMAN SYSTEM.

John T., a young Italian, æt. 20 years, was admitted to St. Francis' Hospital with a badly crushed ankle. With the hope of saving the foot, it was put at rest and the usual treatment applied. The tarsal bones, however, were so badly crushed that they failed to unite. After some weeks sinuses formed, and spicula of bone being discharged, he was put under an anæsthetic and a quantity of diseased bone removed, but without much benefit. He came under my care about nine months after the injury. He was thin, pale and much reduced in strength. His ankle was enormously swollen, with numerous openings of sinuses, from which flowed copious discharges of unhealthy pus. He had persistently refused to have the foot removed, and it was only when he was compelled to choose between his foot and death, that he consented to an amputation. I first tried a Syme, but so fearfully disorganized and pus-infiltrated were the tissues that they separated by their own weight. Finding the articular portion of the tibia also diseased, I finally amputated at the middle of the leg, using only the antiseptic precaution of clean instruments and boiled water. The wound healed by the first intention, and in ten days I found him being measured for an artificial leg. From the day the foot was removed he improved in weight and strength.

Case 2 was also a young Italian, who was admitted to Mercy Hospital with a compound comminuted fracture of the lower third of the leg. The lower portion of the tibia projected an inch or so through the wound and was impacted there. He had been injured three weeks before, and one week of the time he had spent in the Homœopathic Hospital. His friends had taken him home from there and I suppose had tried to cure him themselves. When I saw him first he was fearfully reduced, with an immense bed-sore on his back, half of his foot gangrenous and emitting a most sickening odor. The wound at the seat of fracture was in a most foul and unhealthy condition. Pus had infiltrated the tissues in every direction. He was given $\frac{1}{4}$ gr. of morphine hypodermically, the A. C. E. mixture administered, and the leg amputated at the middle. He made a speedy recovery, the leg being healed before the bed-sore. A large phlegmonous abscess formed

over his left breast, but healed promptly after free evacuation and bichloride injection.

Case 3 was a most desperate one. A man 52 years of age was admitted to Mercy Hospital, with a compound fracture of the lower third of the femur. He was emaciated to the most extreme limit, his face haggard and eyes wild, but glazed and sunken in their sockets; his skin cold and moist, and his pulse small, thin, frequent and very difficult to count; his tongue dry and parched, could scarcely be protruded through his bloodless lips. He had an immense bed sore over the lumbar region, extending down to the coccyx and over the buttocks. His right leg below the knee was discolored and had a large, foul ulcer. His left leg was twice its normal size. At the seat of fracture, at the lower third of the femur, were two large openings communicating with the bone, and through which was a rubber tube half an inch in diameter, and at least a yard in length, this extending almost a foot and a half outside of each of the wounds! Below the knee the leg was immensely oedematous and was confined in a large wooden crate, or cradle, extending from the knee to the ankle. At the lower part it had cut through until the tendo Achillis was exposed, although, well padded at the sides! This contrivance, which looked something like the boxes they transport peaches in, was so arranged as to swing the limb, and hence keep up all the motion possible at the seat of fracture. The stench from the wounds was almost unbearable, and they were literally alive with maggots, even the immense so called drainage tube being absolutely occluded with them.

This poor man had been injured nearly five weeks before, and, I say it with shame, had been attended daily all that time, by two men called doctors. He lived about thirty miles from the city, and the day before his "doctor" had told his friends "he had done all he could for him and they had better take him to the city." And he had endured the long trip in this awful condition.

With but the faintest hope of doing him any good, I gave him several drachms of whisky hypodermatically, and administered the A. C. E. anæsthetic. On examining the wound, we found that the whole thigh was infiltrated with the most putrid pus infested with maggots. Not less than two quarts of this was expressed, as two large sinuses extended, one in front to Poupart's ligament, and the other far up in the gluteal region. These sinuses were an inch or two in diameter, and were surrounded with a foul, greyish-black membrane. The bone was broken in several fragments, which were lying loose in the wound. Although I had not contemplated amputation, as the patient's condition forbade it, yet I thought it worse than useless to try to rally him under his present condition, and so amputated at the upper third of the thigh. I washed the wound with

water so hot that it instantly seared, as it were, the ends of the cut vessels, and afterwards drenched the sinuses time and again with water as hot as I could bear my hand in, and dusted the whole freely with iodoform. The flaps, of course, were left open. He reacted slowly, but Dr. McMann gave him hypodermics of whisky and ether almost every half hour during the night, and enemas of hot milk and whisky, with all the artificial heat he could get around him. He rallied perfectly, and although his convalescence was long and tedious, he recovered, eventually, with a new lease of life.

It seems astonishing in all three of these cases, and especially the last, that, notwithstanding the great quantity and deadly quality of the pus, nature had so carefully guarded them from pyæmia. It is also noteworthy that, although antiseptic precautions were almost impossible, yet the antiseptic dressings of the wounds certainly had much to do in the success of the operation.

DR. KOENIG: I feel like congratulating Dr. Davis on the result of his surgical interference, but I also feel like asking him to change the subject of his paper. He stated that he simply wanted to give us an evidence of the recuperative power of nature. It seems to me the subject should be the life-saving power of mercury. We have all seen how nature bungles, how she is unable to save life without the aid of the scientific physician. I think we should divide the credit, giving a large portion of it to mercury, or other antiseptics, and less to nature.

To be concluded.

SPECIAL CORRESPONDENCE.

Differential Criticism of the Spinal Cord.

To the Editor.—Nearly three-fourths of a century ago Londe, by very careful experimental research, concluded that sensory impressions were conducted solely by the posterior column of the spinal cord to the brain, and in his day this theory was generally accepted. Soon after Londe, or in 1823, Bellingier demonstrated by experiments on living animals that sensory impressions were conducted to the brain through the gray matter of the cord exclusively.

Flint, in his text-book, p. 678, makes the following inquiries: 1. Does or does not the white substance of the posterior column of the cord conduct sensory impressions to the brain? 2. Does the entire substance of the cord act as a conductor of sensibility? 3. Does both the gray matter of the cord and the white substance of the posterior column act as conductors, or does either one act to the exclusion of the other?

"These questions," he further says, "may now be considered as definitely answered by the most positive and unmistakable results of experiments upon living animals, which leave no doubt with regard to the part of the cord which acts as conductors of sensory impressions." To the first query he says that whatever may be the function of the posterior white columns, they do not serve as conductors of sensory impressions. The sec-

ond question is as positively answered in these words: "When the gray matter is divided with very slight injury to the white substance, sensibility in the parts below the point of section is totally destroyed." And the answer to the third question is deduced from the answers to the first two. What can be more positive!

Again, Ranney, "Applied Anatomy of the Nervous System," p. 300, says, "The sensory fibres found in the posterior root (of the spinal cord) ascend in the column of Burdach for a short distance only, when they pass into the gray matter of the posterior half of the cord."

Other American authors are equally positive in stating that the sensory tract of the spinal cord is the gray matter, and almost certainly that portion of the gray substance near the central canal.

As students of medicine and seekers of truth, we have accepted this without mental reservation.

In opposition, however, to the foregoing, Byron Bramwell, of Edinburgh, in his recent work on the spinal cord, is positively contradictory.

By examining this work it will be found that Figs. 29, 30, 34, 38, 50 and 61, distinctly show the sensory tract of the cord to be the posterior white column, or the column of Burdach, and not the gray substance, according to Flint, Hammond, Ranney and others.

The explanatory text in Bramwell confirms the cuts in every instance. I am after the truth, if it is known. Who is right? STEWART LEROY MCCURDY, M.D.

Dennison, O.

Shall The Journal be Removed to Washington?

To the Editor:—I prefer Chicago.

WM. T. CORLETT, M.D.

Cleveland, O.

To the Editor:—I have waited until the present before expressing my opinion upon the action of the Trustees of THE JOURNAL, at their late meeting, advising that at the end of the present year, THE JOURNAL should be permanently established in a central office at Washington. The only argument offered in favor of the change was by one of the new Trustees who stated that he voted for it because he was pledged to that course of action before his appointment.

Few know better than myself the events which led to the establishment of THE JOURNAL and its location in Chicago. It was but natural to expect that there would exist a rivalry between the leading centres of our great country for its possession, since it is easy to understand the power and influence which such a journal might exert if made the exponent of local interests. Fortunately for the Association and the Nation, the guardians of the interests of THE JOURNAL have thus far been enabled to hold in restraint all ulterior influences, and have treated the interests of the different sections of our country with impartial justice.

There can be no doubt that a very much better journal could have been furnished by the expenditure of a much larger sum of money, but no one can now question the wisdom of the Trustees and the self-sacrificing economic care of our first editor, Dr. Davis, in adopting the "pay as you go system."

In its rapid growth and development, our journal is now justly considered the peer of any of the great weeklies of the Eastern cities, and under wise and energetic control it should become the leading exponent of the best medical thought in America. With such a history and such a promise of future good, what gain is to be expected by a change of location to Washington?

Is it because Washington is the capital city and the centre of the political influences of our country? Some have felt that already the greatest danger to our Association and its journal lies in the fact that a political ele-

ment has entered into its organization and is seeking control. If there is reason for apprehension in this direction, it would be a strong argument for its removal from Washington had it been established there instead of at Chicago.

Is it because Washington is a greater literary, medical, or educational centre than Chicago? We have all watched with amazement the wonderful growth of Chicago, until she has become the second great city of our country, and great as she is in wealth and commercial activity, those who know her best, know that she is lavishing her money upon libraries, art collections, universities, and schools of learning, until we in the East look with jealous eye at our fast departing preëminence. No city in the world has equalled her in growth and prosperity, and none give greater promise for the future.

As a center for ease of access, or for rapid distribution, Washington offers nothing in consideration. Whatever else may be said of medical journalism in common with every other publication, it must be considered as a business enterprise. "Can it be made to pay?" was the doubtful question asked at the baptism of our journal. "What are the profits already?" is the query meeting every suggestion for improvement, and "is it possible to defray the necessary expenditure?" The income of THE JOURNAL is dependent upon two factors, the subscription list and the advertising sheet. Can the Trustees show that in either respect the income is likely to be increased by its removal to Washington? The subscription list will depend, in a very large degree, upon the character of THE JOURNAL, and no one can doubt that its interest and value can at least be made equal in its present location to that of any other. I do not suppose that any one will advance the argument that it is really necessary to remove THE JOURNAL to Washington in order to provide for it a competent editor.

It is equally clear that THE JOURNAL can be published as economically in Chicago as in any other of the great centres of our country.

When we take into consideration the legitimate income to be derived from the advertising department, it requires little proof for the demonstration that the larger the local centre from which a journal emanates, the greater is the value of that journal for advertisers. On this account our journal is especially fortunate in having its home in Chicago, and we cannot help thinking that it would be most unfortunate and detrimental to its interests to remove it to Washington.

Boston, New York, Philadelphia, Baltimore, Cincinnati, Louisville, Nashville, St. Louis, each have their medical weeklies dependent largely upon local interests. Remove our journal from Chicago and the field will be open for the establishment of another weekly medical journal dependent in a large degree for its support upon its legitimate advertising.

Let the business interests of our journal continue to be transacted upon strictly business principles; secure for its management the best talent to be obtained and trust the future for its greatly increased usefulness. When the time comes that our finances will warrant the expenditure of a large sum of money for buildings and the accessories for a large publication house, then, and not till then, let the Association discuss the question of an elaborate home. For the present, at least, our Trustees have more vital subjects demanding their attention in increasing the value of THE JOURNAL and making it the worthy repository for the best medical thought and science of the new world.

HENRY O. MARCY, M.D.

116 Boylston St., Boston, Mass.,
January 19, 1891.

To the Editor:—Let THE JOURNAL remain in Chicago. It is certain that the place wherein it is published will largely impress its own character upon it. The fact that

Chicago is not only the geographic and railroad centre of our country, but is also a great metropolis, with immense and constantly increasing medical, literary and business interests springing up within it and flowing toward it from all parts of the Union, will give to THE JOURNAL an *état* and high professional position, that will add greatly to its power, and widen its influence beyond anything that could possibly be hoped for were it a fixture in Washington.

It is appropriate that the representative of American medicine should have its home in the representative American city, which is Chicago. This city can also place at the disposal of the management a wealth of resource second to but one in this country, and it not now will very soon be first in this respect. In comparison with this anything Washington could ever offer would seem poverty-stricken.

ARTHUR YOUNG, M.D.

Prescott, Wis., January, 1891.

To the Editor:—As an old member of the Association I implore all those who are in favor of its removal to let THE JOURNAL remain in Chicago.

D. COLVIN, M.D.

Clyde, N. Y., Jan. 20, 1891.

To the Editor:—As the question of the removal of THE JOURNAL to Washington seems to be agitating the subscribers of same at present, I would join my voice with those wishing it to remain in Chicago, as this city will without doubt become the "centre" of the North American Continent in time.

D. L. SAUERHERING, M.D.

Wausau, Wis., Jan. 21, 1891.

To the Editor:—Please record my vote in favor of continuing the publication in Chicago.

GEO. E. FELL, M.D.

Buffalo, N. Y., Jan. 21, 1891.

To the Editor:—In regard to removing THE JOURNAL to Washington, I prefer it to remain in Chicago, and believe that the entire membership should have a vote when the question is decided.

FRANK DEVILBISS, M.D.

Spring Garden, Mo., Jan. 24, 1891.

To the Editor:—As the question of the removal of THE JOURNAL from Chicago to Washington is forced upon the members of the Association, it is clearly plain to me that Dr. Dimmitt's plan, as offered in THE JOURNAL of January 17, is the only safe and true plan of procedure. In this manner alone can all the members have a voice upon this most important question; and it will beat the Australian method of voting altogether.

In my opinion THE JOURNAL should remain in Chicago, where it is now prosperous and self-sustaining. Certainly let it remain where it is long enough for the colored gentleman now in the woodpile to get a good crop of wool on his head.

HERBERT JUDD, M.D.

Galesburg, Ill., Jan. 24, 1891.

To the Editor:—Why should the place of publication of THE JOURNAL be changed to Washington?

What reasons have we to suppose its financial and editorial success would be more certain in Washington than at Chicago?

Why should the list of subscribers be increased because THE JOURNAL is published at Washington?

For what reasons may we expect more business sagacity, and greater editorial skill in its management at Washington, than at Chicago?

These are practical questions, which cannot be answered

by asserting that the success of THE JOURNAL is at present, and certainly at the time it was started, neither a fact nor a certainty. But only individual assertions and opinions. If those members of the Association who desire it changed to Washington will raise a guaranteed fund of \$25,000 for five years, there will be a tangible reason for such a change.

As a purely business matter, THE JOURNAL cannot be changed to Washington, without loss. It will provide or guarantee against this. This has already been said of very serious, no one can determine, but who will take the risk. If THE JOURNAL has a surplus fund of \$25,000, it could insure itself, but without this, who will be responsible?

THE JOURNAL must be conducted and managed the same as any other business enterprise, on business principles. All changes in its management and place of publication should be based on business principles, and not on individual opinions or personal preferences.

What all members of the Association should have in positive facts is that THE JOURNAL, the more prosperous in Washington than at present, is beyond all reasonable question or doubt, then it is a question of business, not of prejudice or feeling.

When such evidences are presented I shall vote for a change, is a duty. But until they are, it is equally my duty to oppose any change that has not the best of business reasons and assurances of success.

T. D. CHITTENDEN, M.D.

Hartford Conn.

To the Editor:—The question of the place of publication of THE JOURNAL should be discussed frankly, without sectional or personal prejudice, and with reference to these two considerations:

1. Where can THE JOURNAL, other things being equal, be best edited?

2. How can THE JOURNAL, other things being equal, best serve the highest interests of the Association?

Taking up first the question as to how THE JOURNAL can best serve the interests of the Association, the answer is:

1. By not identifying itself with any local interest whatsoever.

Upon this head, one needs only to consult the files to see that THE JOURNAL has persistently biased itself to the level of a local Chicagoan journal, both in editorial and news columns. Were it to do the same thing in Washington, Philadelphia, New York or Boston—or any other where—it would be equally reprehensible.

2. By presenting the best work of the best men in America in the columns devoted to original communications.

Whoever the fault may be, one needs only to consult the files, to see that THE JOURNAL has not attracted the best work of the best men, North, South, East or West. Undoubtedly it has had very many superior papers from very many superior men—but the proportion of such papers has never been what it ought to be in THE JOURNAL of THE AMERICAN MEDICAL ASSOCIATION—an Association which numbers among its members "the best men in America."

3. By rejecting papers which fail to come up to the high standard of a leading medical journal.

One needs only to consult the files to see papers which present nothing new and nothing useful, and do so in a very tedious manner. No questions of policy should permit the entrance of one such paper into the columns of THE JOURNAL, which stands as the representative of the thought and knowledge of the physicians of America. If any of us should read such a paper at a meeting, the editors should be empowered to suppress it, or at least to present it in abstract only.

4. By presenting full, concise, well-edited abstracts of the important communications in other journals, Ameri-

can and foreign; which abstracts should be specially prepared by competent men, and should be reasonably timely in their appearance. Nonsensical and worthless communications to other journals should not be quoted.

One has only to consult the files to see that *THE JOURNAL* has from the first been lamentably weak in this department. Latterly there has been improvement, but even now the majority of the abstracts are second-hand or even third- and fourth-hand—and ridiculously inadequate.

5. By presenting well-informed and thoughtful editorial comment upon questions of importance.

This is and always has been the strongest feature of *THE JOURNAL*, as at present conducted.

Summing up, then, we find that in its present location *THE JOURNAL* has not been best edited.

Would removal improve matters? It seems to me that it would for the following reasons:

1. Washington is the National Capital. It belongs to all sections alike, and the temptation to debase *THE JOURNAL* into a local organ would not exist.

2. At Washington the treasures of the Surgeon-General's Library and the National Museum would be at the disposal of the editorial staff. This inestimable advantage to competent editors exists nowhere else.

3. At and near Washington are many of the best equipped students and investigators who could be called upon for special assistance when necessary, and who would have, as already stated, the proper facilities for rendering valuable assistance.

4. As soon as the best men saw that the editorial status of *THE JOURNAL* was raised they would be only too glad to have their best work appear in its columns. North, South, East and West would alike contribute, and North, South, East and West would alike subscribe. Increased revenue would mean ability to improve still further.

5. Only by concentration can the best work be done. America must have a scientific centre. Let New York, Philadelphia, Chicago and other local centres improve themselves to the highest point possible for local centres—and all unite to improve to the utmost the one National centre—Washington.

Finally as the defects in *THE JOURNAL* (which are not now mentioned for the first time, but have been forcibly shown year after year by at least one Western physician of deserve eminence, Prof. Conneys of Cincinnati)—as these defects are not due to the *personnel* of the editorial staff (which could not be better) they must be due to restrictions imposed upon the editors by the locality. These restrictions would be equally great at New York, Philadelphia, Boston or Baltimore, as at Chicago. They would not exist at Washington. With equally good editors, unhampered by locality, *THE JOURNAL* would soon be what it ought to be.

In this very frank communication, I have had no desire to reflect in any way upon the able editorial staff, for I must admit that with the limitations imposed upon them, they have done much better than any one had the right to expect.

SOLOMON SOLIS-COHEN, M.D.

Philadelphia, Jan. 26, 1891.

NECROLOGY.

DR. FRIEDRICH SALZER, of the Vienna School, died suddenly November 30, at the age of 63 years. For twenty years he had been one of the professors of surgery, and in recent years had been chief of the second division of the Allgemeine Krankenhaus to which institution the death of Dr. Salzer will be a heavy loss. He was one of

those fortunate men in whom a consummate surgical skill was joined to a remarkable success in the results of his operations, a conjunction that is by no means always present among those who wield the knife. Salzer did not have the same facility with the pen as with the scalpel, and contributed comparatively little to surgical literature. One of his sons, Dr. Fritz Salzer, is at the present time professor of surgery at the University of Utrecht.

DR. JOHN DAVIS, of Cincinnati, died December 25, aged sixty-six years. He was a graduate of the Medical College of Ohio in 1843. He was prominent in public affairs in his city, having been until quite recently president of the law and order league.

MR. HUGH OWEN THOMAS, the surgeon of Liverpool, died January 6, 1891. He was an orthopedist of the first rank, whose writings and appliances have long been known in every quarter of the civilized world. In recognition of the value of his accomplishments in his difficult specialty he was elected an honorary member of the American Orthopaedic Association in September last.

SURGEON HENRY M. MARTIN, U. S. N., died in Philadelphia Jan. 16. He was commissioned assistant surgeon March 21, 1870, and made his first cruise in the West Indies in the Congress. He served in the Nantasket and the Colorado on the North Atlantic station, 1871 to 1873, was promoted to passed assistant surgeon in June, 1874; served in the Alert, Asiatic station, 1875 to 1878, and in the Brooklyn, South Atlantic station, 1881 to 1884, and was promoted to surgeon in April, 1884. His last cruise was in the Swatara, Asiatic station, 1887 to 1890, from which ship he recently returned in ill health and was placed on the retired list.

DR. ALEXANDER T. AUGUSTA, who died in Washington, D. C., December 21, was a native of Pennsylvania, and a graduate in 1856 of the Trinity Medical College, Toronto, Canada. He was the only one of his race during the Civil War who received a commission as surgeon, his command being the Seventh U. S. Colored Infantry, which was organized at Baltimore, Md., to serve three years. He, among numerous officers who had distinguished themselves, received a brevet March 13, 1865—in his case that of Lieut.-Colonel, and at once devoted himself to the duties of his profession.

DR. CHARLES A. MILLER, who received his degree from the Medical College of Ohio, in 1862, and who was mustered out of the U. S. Service on expiration of term of service September 13, 1864, as Assistant Surgeon of the 34th Ohio Vol. Infantry, died November 21 at the Longview

Asylum for the Insane, near Cincinnati, O. He was born in Hamilton County, Ohio, and educated in Cincinnati, where he engaged in practice, soon after the war, and there remained until appointed Superintendent of the Longview Asylum nine years ago. Dr. Miller was a naturalist of national reputation and had one of the finest geological cabinets in the country. He had been long in poor health, suffering mainly from diabetes, to which was added a gangrenous condition of one foot. From this latter complication he recovered, but without benefit to his general constitution.

DR. JAMES L. STEWART, of Erie, died December 7, aged 65 years. He was of Scotch-Irish descent and born near Pittsburg. He graduated from the University of Pennsylvania in 1848, and went to Erie just forty years ago. During the late war he served four years as a surgeon of volunteers, having charge during a portion of that time of one of the large army hospitals near Washington. He was prominent in pension matters for many years and in many societies, both medical and charitable. He was repeatedly the president of the medical organization of his county and of the State Medical Society in 1879. He was chief surgeon of the St. Vincent's Hospital and of the county correctional buildings. Surgery was his favorite field of practice, in which he did some notable work, especially in the excision of nerves.

DR. HENRY SALVIN GILL, born in Allston, England, 38 years ago, died in New York of pneumonia, January 16. He was a graduate of the University of Edinburgh and of the College of Physicians and Surgeons, N. Y. He was a cousin of the Archbishop of York.

DR. JOSHUA KENDALL, of Seymour, Conn., died at his home January 19, at the age of 84. He settled in Seymour in 1832 immediately after his graduation from the Castleton Medical College, Vt., and resided there ever since. He was one of the best known men in the county. His death was the result of an operation for the removal of cancer.

DR. JOSEPH PARRISH, of Burlington, N. J., died on January 15. He was a son of the celebrated Dr. Joseph Parrish, of Philadelphia, and graduated at the University of Pennsylvania in 1844. He organized the Pennsylvania Sanitarium for the Cure of the Inebriates, located at Media, and was also at the head of a similar institution in Burlington. He was the founder of the American Association for the Study and Cure of Inebriety, established in 1870, which awakened interest in England, and in 1872 a committee of the Houses of Parliament was appointed to investigate the subject, and Dr. Parrish, and the late

Dr. Dodge, of New York, were summoned to appear and testify as to their knowledge of the treatment of inebriates. He was a member of the American Medical Association since 1847.

BOOK REVIEWS.

EPILEPSY: ITS PATHOLOGY AND TREATMENT.

Being an Essay to which was awarded a prize of four thousand francs by the Académie Royale de Médecine de Belgique, December, 1889. By HOBART AMORY HARE, M.D., etc. Philadelphia and London: F. A. Davis. 1890. Pp. 228. \$1.25.

This little volume is No. 7 of the Physicians and Students Reference Series, and is well deserving of the prize accorded it. The author displays a fair and judicial spirit in treating the many conflicting opinions and theories which confront a consideration of the subject and from an enormous mass of literature has gotten that which is most reliable and of practical value. To anyone having the management of a single case of epilepsy this monograph would be invaluable.

THE INTERNATIONAL MEDICAL ANNUAL AND PRACTITIONER'S INDEX for 1890. Edited by P. W. Williams, M.D., Secretary of Staff, assisted by a corps of thirty-six collaborators—European and American—specialists in their several departments. 600 octavo pages. Illustrated. \$2.75. E. B. Treat, Publisher, 5 Cooper Union, New York.

The eighth yearly issue of this handy reference one-volume manual is at hand. In its Alphabetical Index of New Remedies and its Dictionary of New Treatment it richly deserves and perpetuates the well-earned reputation of its predecessors. In this volume its corps of department editors has been largely increased, and important papers upon Thermo-Therapeutics, Electro-Therapeutics, Sanitary Science in city and country, and the Medical Examiner in Life Insurance are features of special interest. It is truly a helpful volume, a *résumé* of the year's progress in medicine, keeping the busy practitioner abreast of the times with reference to the medical literature of the world. While there is a generous increase in size and material, the price remains the same, \$2.75.

A PRACTICAL TREATISE ON IMPOTENCE, STERILITY AND ALLIED DISORDERS OF THE MALE SEXUAL ORGANS. By SAMUEL W. GROSS, A.M., M.D., etc. Fourth edition. Revised by F. R. STURGIS, M.D. Philadelphia: Lee Brothers & Co. 1890. 8vo, pp. 173. \$1.50.

The subject matter of this small volume, so generally neglected or not even mentioned by

medical teachers and writers is carefully, plainly and suitably handled by the author. The chapters are on Impotence, Sterility, Spermatorrhœa and Prostatorrhœa respectively, embracing many clinical reports which give vitality to the work. The statement is made that of barren marriages one in six is due to sterility on the part of the husband, an opinion amply sustained elsewhere, the importance of which is self evident. It is possible that undue weight is attached to irritable and sensitive conditions of the deep urethra which, in the author's experience, are almost invariably found, and to the correction of which his energy is always primarily directed. The book is heartily commended to all and without doubt deserves the popularity which has produced a fourth edition in so short a time.

IRREGULARITIES OF THE TEETH AND THEIR TREATMENT. By EUGENE S. TALBOT, M.D., D.D.S., etc. Second edition. Revised and Enlarged with 234 Illustrations, 169 of which are original. Philadelphia: P. Blakiston, Son & Co., 1890. Pp. 261. \$3.00.

When a technical work goes to the second edition its value cannot be disputed. The book is gotten up in an excellent form and the author writes in a smooth, clear style that is often sought in vain in dental writings. The present volume is in number of pages nearly twice as large as the first edition and divided into Part I Etiology, and Part II Treatment. It is readily to be seen that "constitution causes for irregularities of the teeth" is the writer's hobby, and to it he devotes eighty-six pages, presenting in an interesting and readable way a mass of data from a wide variety of sources. Consanguinity, maternal impressions and some kindred topics are made to give support to his theories in a way that the unsettled state of knowledge regarding them scarcely warrants, and the allegation that advanced civilization is largely responsible for dental malformations seems open to debate. The chapters on treatment contain practical and well illustrated directions that can not fail of proper appreciation by practicing dentists.

MISCELLANY.

Official List of Changes in the Stations and Duties of Officers Serving in the Medical Department, U. S. Army, from January 17, 1891, to January 23, 1891.

Capt. Edwin F. Gardner, Asst. Surgeon, is relieved from duty at Pine Ridge Agency, S. Dak., and will proceed without delay to Ft. Riley, Kan., and report for temporary duty to the commanding officer of that post. By direction of the Secretary of War. Par. 10, S. O. 17, A. G. O., Washington, January 21, 1891.

Capt. Francis J. Ives, Asst. Surgeon, is relieved from temporary duty at Pine Ridge Agency, S. Dak., to take effect when his services can be spared by the command-

ing officer of the troops there stationed, and will then return to New York City and resume his leave of absence. By direction of the Secretary of War. Par. 9, S. O. 17, A. G. O., Washington, January 21, 1891.

Official List of Changes in the Medical Corps of the U. S. Navy for the Week Ending January 24, 1891.

Surgeon R. C. Persons, ordered to the U. S. S. "Concord" February 10.

ORIGINAL ARTICLES.

A STUDY OF STERILITY, ITS CAUSES AND TREATMENT.

Being an Essay which received the First Prize of the Alumni Association of the College of Physicians and Surgeons, Baltimore.

BY THOS. W. KAY, M.D.,

OF SCRANTON, PA.

INTRODUCTORY.

General Remarks.—"Be fruitful, and multiply, and replenish the earth," was the first command given to man, and it is as binding to-day as it was at the close of the creation, for a neglect of its fulfilment necessarily implies an extinction of the species. It is the desire, unconscious it may be, to fulfil this command that prompts man to seek the society of woman. The late Dr. Carpenter, of England, says "love" is based on the innate desire for offspring. This fact was recognized as early as the time of Soranus, who says. "As most marriages are not contracted for love, but to beget offspring, it is unwise, in the choice of a wife, to consider her social standing and riches rather than her fitness for bearing children."

Sterility is one of the most potent factors in producing domestic unhappiness, and was so as long ago as the time of Abraham, when, having begotten a child by Hagar, Sarai "was despised in her eyes" because of her unfruitfulness.

Historical.—Though Jacob loved Rachel better than Leah, he turned his affection to his less comely wife after she had borne him a son. After having brought forth several children, Leah exclaims: "Happy am I, for the daughters of men will call me blessed. God hath endowed me with a good dowry, for I have borne him six sons." The barren Rachel, feeling keenly her disgrace, cries in her anguish, "Give me children or I die," after which we are told that "the Lord saw that she was hated and opened her womb." Among the ancient Greeks, as among the Jews, sterility was considered a disgrace, and was a frequent cause for divorce, the unfortunate woman being looked upon as a lower, or imperfectly developed, being. Travelers, among the inhabitants of nearly all uncivilized countries, remark that the pregnant women take pains to show, and

frequently point with pride to, their enlarged abdomens. In Angola, says Livingstone, sterility is such a disgrace and such a cause for ridicule, that the unfortunate women are frequently driven to suicide. Pallas states that the well-to-do Circassians give a dowry to their daughters only after they have proved themselves fruitful.

Among the Moslem inhabitants of Turkey, divorces are very common, and in most cases sterility is found to be the cause. It is from the ranks of these unfortunates that the native prostitutes are obtained.

Sterility and fecundity were frequent themes for the ancient historians and poets. In the *Susruta*, a book of ancient India, conception is said to "take place easiest at the menstrual period, for at this time the mouth of the womb is opened like the blossom of the water-lily in the sunshine." In the Bible we find sterility frequently mentioned, and examples of it are recorded, with remedies for its relief. The Talmud also makes many allusions to it and its remedies. Sterility is frequently mentioned, and discussed at some length, in the works of Hippocrates. Celsus, Pliny and Aristotle also devote some space to it, but enter into the subject less fully than Hippocrates. Paulus Agineta has much to say on the subject, and devotes some space to the subject of diseases of the female organs of generation. From the works of Maimonides, we know that the subject was frequently mentioned in the writings of the Arabs.

We see, then, the importance that has been attached to it from the earliest times to the Middle Ages, and from that time to the present the question has been gaining in weight.

But what is it?

Definition.—The term "sterility" is applied to both the male and the female, and must not be confounded with impotence, which indicates a physical inability on the part of the male to fulfil the marital rights.

Sterility may be congenital, where the woman, after reaching the age of puberty, has maintained the marital relations for three years without becoming pregnant; or acquired, where, after having borne one or more children, she remains three years, while subject to intercourse, without re-conceiving. By some the term has, in a wider sense, been applied to all who, though becoming

pregnant, are unable to bring forth a healthy living child.

Some English writers use the term "only child sterility" to designate sterility acquired after the first birth.

In very few fruitful marriages is the first birth postponed later than the third year. Kisch collected the histories of 556 fruitful marriages and found that, in 156 of these, the first birth occurred in ten months after marriage; in 199, it occurred between the eleventh and fifteenth months; in 115, between the sixteenth and twenty-fourth months; in 60, between the twenty-fourth and thirty-sixth months; and in only 26, or 2.6 per cent., did it occur after the third year. Duncan gives seventeen months as the average time between marriage and the first birth for the women of Edinburgh and Glasgow. Ansell places it at sixteen months, and finds that less than 5 per cent. bear their first child after the third year. The justice, then, of classing those women as sterile who have not become pregnant during the first three years of married life, is apparent.

It may also be remarked, from the above statistics, that impregnation at the first approach of the male, the rule in brutes, is the exception in man.

Frequency.—The frequency of sterility is much greater than it is generally supposed to be. Of 495 marriages among the English aristocracy, Simpson found 81, or about 16 per cent., sterile. Kisch inquired into the histories of 626 marriages among the royalty and highest classes of Europe, and found sterility in 70, or nearly 12 per cent. The figures for England are large because of the necessity, among the nobility, of marrying near relatives. Ansell, Sims, Simpson and Wells place the general average of sterility, for marriages in all classes, at about 12.5 per cent. Hedin thinks this too high for Sweden, where he claims only one-tenth of the marriages are sterile.

Grünwaldt has collected some very interesting statistics on this subject. After excluding, from 1,500 women suffering from uterine diseases, all virgins, widows, and those over 35 years of age, there remained 900 married women, of whom 500 were sterile. In about 200 of these the sterility was congenital, while it was acquired in the remaining 300. This gives uterine disease as the cause of 60 per cent. of the cases of sterility, and one of every three married women, who suffer from uterine disease, will become sterile.

One must not always look for the causes of sterility in the female, for, as has frequently been the experience with all gynecologists, after having subjected the female to a long course of treatment, the male has been found to be the one at fault. Of 40 unfruitful marriages, Kehrér found the man at fault in 16, or about 35 per cent., and he claims that in a still larger per cent. the male is the indirect cause by transmitting the gonor-

rhœal or syphilitic poison to the female, thus setting up changes which militate against conception.

Courty gives the relative frequency of the seat of the causes of sterility in the male and female as 1:10, Duncan gives it as 1:8, and Noeggerath places it as high as 8:14.

Fetal Development of Genital Organs.—To understand fully the causes and treatment of sterility, it is necessary to have, at least, a rudimentary knowledge of the development of the organs of generation. About the end of the third week, after the ovum becomes impregnated, the allantois begins to develop, and communicates, by the urachus, with the primitive intestine. As the sixth week approaches, the urachus dilates in its lower portion, so as to form the bladder, which communicates with the rectum by a canal—the future urethra. The Wolffian bodies are found, as early as the third week, on either side of the primitive vertebrae. At first they act as primitive kidneys, their ducts emptying into the bladder, but later on they disappear, with the exception of a small portion of each, which can be seen, between the ovaries and Fallopian tubes, as the organs of Rosenmüller. Between the fifth and sixth weeks, two small glandular bodies, formed from the germinal epithelium, begin to make their appearance to the inner side of the Wolffian bodies. These are the genital glands, and they are covered by the peritoneum which attaches them, as a mesentery, to the Wolffian bodies. With time, the genital glands develop, and at the end of the sixth week they can be recognized as ovaries. They remain, however, in the abdominal cavity till the ninth month, when they descend into the pelvis. Developing contemporaneously with the ovaries, we find the conduits of Müller, situated in front of and to the inner side of the Wolffian ducts. It is from the upper portions of these conduits, extending from their superior closed extremities to that point where the lumbar ligament is attached to the Wolffian bodies, that the Fallopian tubes are formed. In their lower portions the conduits of Müller unite, in a common body, with the Wolffian ducts, to form the genital cord, in which the conduits of Müller are situated, to the rear and separated from each other by a partition.

The absorption of this partition forms the utero-vaginal canal, in which, until about the fifth month, no distinction can be made between the uterus and vagina. It is from those parts of the conduits of Müller, situated between the genital cord and the lumbar ligament, that the cornua of the uterus are formed. At first there is no lower, external, opening to the intestine, but gradually an involution of the epithelium dips down, and, about the fourth week, the septum disappears. At this time the intestine, behind, and the urachus, in front, open into the common cloaca. About the sixth week, a transverse septum is formed across the cloaca, dividing it into the rec-

tum, posteriorly, and the urogenital opening, anteriorly. The upper portion of the bladder receives the two ureters, while the conduits of Müller and the ducts of Wolff empty into its lower portion. That portion situated between the openings of the four ducts and the point where the bladder empties into the cloaca is the urogenital sinus, which forms the vestibule of the vagina. At the junction of the vestibule and the vagina, a fold of mucous membrane—the hymen—is finally formed, which, partially or wholly, closes the opening to the vagina. From these fetal parts all the organs of reproduction of the female are developed, and, bearing them in mind, it will be easy to account for all malformations of the female genitals, a common cause of sterility.

Ovulation.—No organs of the body exert as great an influence over physical development as the ovaries. At birth they are small, smooth and flat, but as age advances they enlarge, and become oval and tense. This is in large part due to the increase in size and approach to the surface of the Graafian follicles, to allow their easy rupture for the discharge of the ova—ovulation.

Menstruation.—Menstruation usually begins about the same time and accompanies ovulation throughout the child-bearing period. It consists of a discharge of blood and detritus, which comes from the uterus, and is probably due to a disintegration of the uterine mucous membrane, preparatory for the implantation of the ovum.

After ovulation has been established, the ovaries assume a nodular appearance due to cicatrices left after the discharge of the ova, and this condition remains till late in life, when they atrophy and present the appearance of short and thickened bands.

Puberty.—As the time for the first menstrual period approaches we find the breasts enlarging, the nipples becoming more prominent, the vagina growing more roomy, and the uterus increasing in size. The pelvis broadens out, the hips and thighs increase in size and become rounder, and hair begins to make its appearance on the pubes. This is puberty, which indicates the time about which impregnation first becomes possible.

Relation of Ovulation to Menstruation.—The relation of menstruation to ovulation has often been discussed, and is still an unsettled question, but it can be asserted with certainty that menstruation is due to ovulation, while the latter is independent of the former. Conception may take place in girls, before the menses have made their appearance; in nursing women, while they are absent, or in females after the establishment of the menopause. In all women, however, with few exceptions, a suppression of menstruation is established very soon after the removal of both ovaries.

The age at which conception becomes possible

varies greatly in races and individuals. In Persia menstruation is established by the ninth to tenth year; in Syria by the tenth to eleventh year; and on the Guinea Coast by the eighth or ninth year.

Taylor reported a case of conception in a girl of 12 years; Molitor, one in a girl of 9 years 5 months; Rüttel, one in a girl of 9 years; and Kussmaul one in a girl of 8 years. I have met with a case of twins in a girl of 13 years, and I have had reported to me, on pretty good authority, the case of a Damascus Jewess who became a grandmother at 21 years.

Maturation of the female is early in hot, and late in cold countries. Rich food also stimulates, while insufficient or poor nourishment retards it. Girls nurtured in cities, where it is hot and the mental excitement is great, mature at an earlier age than their country cousins. Heredity is a most important factor in this connection, and it is not uncommon to know of many successive generations developing at an early age.

Menopause.—The menopause is established between the 46th and 50th years, at which time we see something of a return to the masculine type—the voice becoming harsher, the breasts undergoing atrophy, and more or less hair appearing on the chin and lip. Those influences which have been mentioned as affecting the establishment of menstruation affect also the establishment of the menopause. The length of the child-bearing period is pretty definite, for where puberty is early the menopause will be early, and *vice versa*.

A few remarkable cases of child-bearing at an advanced age have been recorded. Rush reported one in a woman of 60 years; Dewees, one in a woman of 61 years; Haller, one in a woman of 70 years; and Thibaut de Chauvalon reported one in a woman of Martinique of 90 years.

Copulation.—During copulation, in most of the lower vertebrata, the relative position of the two participants is back-to-belly, the part played by the female being passive throughout; but in man she is more of an active agent, this being rendered possible by the belly-to-belly position. This position also brings the most sensitive parts of the genital organs of each sex in contact. The engorged and sensitive clitoris is drawn down by muscular action so as to come in contact with the penis, while the corona glandis of that organ causes friction against the roughened folds of the anterior vaginal wall.

In many married women, and some virgins, I have found that that part of the anterior wall of the vagina situated just behind the symphysis pubis, is as sensitive as, and in some cases more sensitive than, the clitoris. As friction is continued all of the female organs of generation become engorged with blood, and muscular action is excited. The uterus enlarges, becomes more

cylindrical, and straightens out the axis of its canal. Its external os becomes dilated and round, while the plug of mucus normally closing that opening is expelled. With these changes we have a slight descent of the uterus towards the ostium vaginæ, while it is tilted back nearer the sacrum, so as to bring the utero-vaginal axis closer to a right line. When orgasm approaches the contents of the vulvo-vaginal glands is discharged in jets, and the vagina and uterus take on a rhythmical contractile action, which probably assists the entrance of the seminal fluid, as it is ejaculated over the cervix, into the uterine cavity. It is not improbable that the uterine terminations of the Fallopian tubes may also be opened by these rhythmical contractions of the uterus. On more than one occasion I have satisfied myself as to the existence of this uterine action, when making a not over-careful digital examination of very amorous females. In examining a woman with prolapsus uteri, J. Beck noticed that the os uteri, during sexual excitement, opened and closed convulsively, five or six times, after which it became firmly contracted. This rhythmic action has been observed by Brundell in the vaginæ of rabbits, while in heat.

Seminal Fluid.—The seminal fluid, as it leaves the penis, is composed of secretions of the testes, the prostate, and Cowper's glands, with a small quantity of mucus derived from the urethra. If examined under the microscope many different objects are seen, but the moving spermatozoa, only, are necessary for impregnation. These progress, according to Lott, at the rate of 36 millimetres a minute. Mayrhofer claims that for impregnation it is necessary that the spermatozoa be deposited, during coitus, in the cervical canal where the reaction is alkaline. Sims found that they died in the vaginal secretions within twelve hours, but in the cervical canal he found them alive forty hours after intercourse, and Percy reports a case where he found them alive as long as eight and a half days after coitus. The cilia in the upper part of the cervical canal may assist them in entering the uterus, but their passage through the Fallopian tubes is due to their inherent mobility, as the cilia of the tubes move in an opposite direction.

Impregnation.—The seat of impregnation is difficult to settle. In the lower animals it is known to frequently take place in the Fallopian tubes, and the frequency of extra-uterine pregnancy in woman leads us to infer that it may take place in both the tubes and the ovaries. Löwenthal advances the hypothesis that about every four weeks an unimpregnated ovum passes to the uterus and becomes imbedded in the mucous membrane, where it is impregnated or degenerates. If this hypothesis were true, extra-uterine pregnancy would be almost unknown.

Impregnation consists in the entrance of one or

more spermatozoa into the substance of the ovum.

In the ova of the lower animals, where observations can be made with facility, the presence of only one spermatozoon has been recorded, but several spermatozoa have been observed in the ovum of the rabbit. Keber was the first to record, in the ova of the fresh-water muscle, an opening, or microphyte, for the entrance of the male element. This has been observed in the ova of other animals, and the ova of some of the lower orders has the power of throwing out processes, or pseudopodia, with which they seize and draw in the spermatozoa, but none of these phenomena have been observed in the mammalia.

Passage of Ova to Uterus.—The old theory of the fimbriated extremities of the tubes applying themselves to the ovaries so as to receive the ova, is now known to be only partially true. In many animals the distance between the extremities of the tubes and the ovaries is too great to permit of this. It is now a well established fact that the motion of the cilia in the tubes creates a slow current of fluid in both tubes and peritoneal cavity. Oldham, Rokitansky, Scanzoni and others have recorded cases where the serum passed from the ovary of the one side into the tube of the opposite side. This was proved by the absence or closure of the tube on the side where the corpus luteum existed.

Of four rabbits from which Leopold removed the ovaries of the one and the tubes of the other side, two subsequently became pregnant.

When the impregnated ovum reaches the cavity of the uterus, it is arrested by the folds of the mucous membrane, becomes attached and begins to grow, but if it should fail to become impregnated it degenerates and is cast off.

Necessary Conditions for Impregnation.—For reproduction, then, three conditions are necessary, viz.: 1. A production of healthy ova and spermatozoa; 2. The union of the ova and spermatozoa; 3. The implantation of the impregnated ovum in a uterus fitted for its development. All influences acting, directly or indirectly, so as to prevent the fulfilment of one or more of these conditions, will produce sterility.

(To be continued.)

LUPUS.—Peter Eade, M.D., writes to the *London Lancet* as follows: "It seems to be of interest to record the fact, with which experience has long made me familiar; that the external remedy which has proved the most potent and effective in promoting the healing of lupoid ulcers is the common *creast*, applied to the sore, either in its pure state or made into a poultice with enough hot, soaked linseed to make the application warm and pleasant, and this used continuously for days or weeks.

THE MANAGEMENT OF MAJOR AMPUTATIONS.

Read in the Section of Surgery and Anatomy at the Forty-first Annual Meeting of the American Medical Association at Nashville, Tenn., May 2, 1890.

BY JOHN A. WYETH, M.D.,

PROFESSOR OF SURGERY, NEW YORK POLYCLINIC, SURGEON TO MOUNT SINAI AND ST. ELIZABETH HOSPITALS.

The prevention of hæmorrhage is the chief point in the management of amputations. Second to this the preservation of as much of the length of a limb as possible.

I will presume that in this day the question of the aseptic or antiseptic management of all wounds is no longer open for discussion among scientists; and that as to the question of amputating during the period of shock, it is no more permissible when applied to injury of an extremity than when it follows a perforating wound of the abdominal viscera, and where is the surgeon who, except for the arrest of hæmorrhage rapidly exhausting his patient, will add to the shock of accident the shock of deliberate surgical interference?

I desire to submit to you two amputations in major amputations which I have devised and successfully executed:

1. *Bloodless amputation of the hip.*
2. *Bloodless amputation of the shoulder.*

1. *Hip Joint.*—It is well known that the terrible death rate after hip-joint amputation is chiefly due to hæmorrhage. Compression of the aorta or common or external iliac has not rendered the operation less dangerous. The figure-of-eight elastic bandage of Esmarch carried above the iliac crests or around the abdomen, and the transfixion by a single needle passed in front of the neck of the femur and beneath the vessels, over the ends of which a rubber cord is carried only in front of the thigh, as advised by Trendelenburg, or the figure-of-eight rubber spico of

FIGURE 1.

Fourneau-Jourdan, are improvements on older methods, but are far from satisfactory. Without going into the history of this amputation I submit my method as follows:

The patient being placed in position, with the hip of the side to be operated on well over the corner of the table, the foot is elevated and

an Esmarch bandage applied to drive the contained blood toward the heart. The bandage should not be tightly put on over the seat of the disease for fear of driving septic matter into the circulation. With the rubber bandage still in position, the needles are next introduced.

Two steel mattress needles, three sixteenths of an inch in diameter and a foot long, are used. The point of one is inserted an inch and a half below the anterior superior spine of the ilium and slightly to the inner side of this prominence, and is made to traverse the muscles and deep fascia, passing about half way between the great tro-

FIGURE 2.

chanter and the iliac spine, external to the neck of the femur and through the substance of the tensor vaginæ femoris, coming out just back of the trochanter. About four inches of the needle should be concealed by the tissues.

The point of the second needle is entered an inch below the level of the crotch internally to the saphenous opening, and, passing through the adductors, comes out about an inch and a half in front of the *tuber ischii*. No vessels are endangered by these needles. The points are protected by corks to prevent injury to the operator's hands.

A piece of strong white rubber tube half an inch in diameter and long enough when tightened in position to go five or six times around the thigh, is now wound very tight around and above the fixation needles and tied.

The Esmarch bandage is removed and five inches below the tourniquet a circular incision (Fig. 1) is made, and a cuff which includes the subcutaneous tissues down to the deep fascia is dissected off to the level of the lesser trochanter, at which level the muscles and vessels are divided squarely and the bone sawed through (Fig. 2). All vessels (including the veins) which can be seen are tied with catgut and the smaller bleeding points can be discovered by slightly loosening the tourniquet.

The remaining portion of the femur is now

easily removed by dividing the attached muscles close to the bone and opening the capsule as soon as it is reached. On lifting the end of the bone in the direction of the patient's navel and dividing the cotyloid ligament posteriorly, the air enters the cavity of the acetabulum and greatly facilitates the division of the ligamentum trees (Fig. 3).

FIGURE 3.

The closure of the wound, with proper drainage, follows (Fig. 4). The entire proceeding requires the strict asepsis of modern surgery.

One other important point I wish to emphasize—viz., the advisability in certain cases of doing this operation in *two sittings*.

In one of my cases the patient was greatly exhausted, and after dividing the femur at the trochanter and securing the vessels, fearing the supervention of shock as indicated by the pulse, I closed the wound, which healed by first intention. At the first dressing (on the seventeenth day), the remaining portion of the bone was removed by an incision over the trochanter major. The recovery was uninterrupted.

I should prefer to complete the operation at one sitting, but cases will occur where the danger of shock may be obviated by stopping short of enucleation, leaving this for a week or two, when reaction and convalescence are assured.

In neither of my cases was there any bleeding, and in two additional operations by this method, very recently performed by two distinguished surgeons of this city, there was perfect immunity from hæmorrhage and rapid recovery. *In fact, amputation at the hip joint is now a bloodless operation.*

2. *Shoulder joint.*—I have also applied this same method at the shoulder. One needle is made to transfix the anterior axillary fold away from the vessels, and nerves taking firm hold in the tendon of the pectoralis major. The other pierces the deltoid just below the acromion process and is pointed backward. The arm having been emptied of blood, the rub-

ber tube is tightly wound around the shoulder above the needles. A circular skin flap is made and rolled back to within three inches of the acromion, at which point the muscles and bone are divided and the vessels all secured. The tourniquet is removed and the remaining portions of the humerus enucleated.

PRESERVING THE LENGTH OF LIMB IN AMPUTATING FOR OSTITIS AND OSTEO-MYELITIS.

Within two years it has occurred to me twice to amputate just above the knee for osteomyelitis of the femur secondary to destructive osteoarthritis in the knee joint.

Upon sawing through the femur the medulla, broken down to the consistency of thin soup, escaped like so much thin pus. The canal was much larger than normal, owing to absorption of the inner surfaces of the compact substance. In one case I could have crushed the bone easily between my thumb and finger. In these two instances, with a long Volkmann's spoon, I scraped out the canal thoroughly as high as the trochanter where it ended. I then inserted into the canal a rubber drainage tube with a single lateral perforation one inch from the upper or inserted end. This end reached the level of the trochanter minor.

The wound was closed as usual leaving this long tube projecting through the flap opposite the medullary canal. At intervals of from four to six days the canal was irrigated with 1 to 3000 sublimate solution, by forcing it into the end of

FIGURE 4.

the tube in a continuous stream until it flowed out through the canal outside the tube. The tube was withdrawn from one-half to one inch each week, and the canal gradually filled up with healthy granulation tissue which later was changed into bone.

Both patients recovered with stumps of the fullest possible length.

Although not novel, as I have since learned, I had not known of this method until after it had been put into practice in these two instances.

THE RELATION OF LIFE INSURANCE TO INEBRIETY.

Read before the American Association for the Study and Cure of Inebriety, at the monthly meeting in New York City, Dec. 10, 1891.

BY T. D. CROTHERS, M.D.,

SUPERINTENDENT WALSH LODGE HOSPITAL, HARTFORD, CONN.
EDITOR JOURNAL OF INEBRIETY, ETC.

As introductory to a brief study of this subject some general experience will make clear the conclusions which I wish to urge. During the past fourteen years I have been exclusively engaged in the institutional cure and treatment of inebriates. In the large number of persons of this class who have come under my observation many of them have been insured for large amounts in the best life insurance companies of the country. I have no statistics of the exact number, but I am confident that from a third to one-half of all the inebriates under my care carry insurance policies of greater or less amount.

While the object of all companies is to insure only sound healthy lives, it is evident that this is not the fact in a large number of cases. It has come to my knowledge that many of these cases have been insured after they became inebriates. In one case a man who had been twice under my care for periodical inebriety, secured an insurance of fifty thousand dollars, in the aggregate, in different companies. This man has drink paroxysms and requires treatment every year. In another case an incurable son (of an influential man) who had been under my care a number of times, died from pneumonia following a drink paroxysm; insurance policies of thirty thousand dollars were paid on his life. In another case an inebriate of twenty years' duration, secured fifteen thousand dollars in different companies, shortly after being under my care for four months. Within a year he died from some obscure brain lesion, which came from a drink paroxysm. The insurance was paid.

In a general classification of the cases I have seen who were insured, something like the following seems to be very common: The largest class appear to be invalid or silent partners of mercantile houses; broken down merchants or clerks; men who had occupied business positions, or been prominent in professional circles, but have withdrawn for some reason. Most of these cases acknowledge moderate drinking, and give no evidence of excesses in public or in appearances. Many of these cases are secret drinkers, others are periodical and anticipate the paroxysm by providing for its secret indulgence, away from home in some distant city. After the attack they are temperate for a distinct time and give little evidence of their real condition. Often these cases are strong temperance workers, and make a public exhibition of their faith, and after the sudden disappearance to indulge in a drink

paroxysm appear more enthused than ever for the cause.

A prominent temperance lecturer is a good illustration. He has always two or three "drink storms" a year, of a week's duration. The intervals are filled with most enthusiastic work for reformation of others. He has a large insurance policy on his life and is considered a sound, healthy man. In another case a clergyman with rich relatives, has a fifty thousand dollars on his life, and is a prominent prohibitionist, works with great energy and is a leader of much influence. This man has drink paroxysms in secret every spring and fall of the year. Many cases of active business and professional men drink to great excess at irregular times and away from home. They come often to institutions for a short time under an assumed name, and go away restored. These cases always carry large insurance, and no doubt acknowledge moderate or occasional drinking to the medical examiner. In all probability these men recognize the future peril which may grow out of their secret excesses and thus seek protection from insurance.

In some of these cases the companies are at fault, in others the examiners; often the insured parties have not covered up or concealed the fact of drinking, but the drink storms have not been mentioned. Other cases are men of family, without business, having wealth, and living leisure lives. They are wine and beer drinkers at the table and claim to be only moderate users of spirits. Often they carry large amounts of insurance divided up among many companies. Often they are club men who are comparative fast livers, and while they seem not to be excessive drinkers, they are undoubtedly so in secret. They are generally incurable cases when they come for treatment. Recently a man of this class who had consulted me for drink excesses died, and his family received fifty thousand dollars insurance.

These cases are common in my experience. I fully recognize the fact that notwithstanding all the care and precautions of companies and examiners, a certain number of persons will obtain insurance who are bad, dangerous risks. Companies who admit moderate drinkers, and those who leave the question of risks in these cases to the judgment of examiners, will always have a large number of these dangerous risks, and a larger mortality. One such company became alarmed at their death rates, and from the report of a special examiner on risks, over ten thousand, cancelled in one year thirty-one policies of pronounced inebriates, who had been insured as sound and healthy. Another company who had practically refused moderate drinkers, but left the question open and depended on the judgment of examiners, cancelled twenty-six cases of the same character all carrying large policies. The reason for these errors and mistakes is evident from the

medical instruction to examiners by some companies. This is illustrated in the advice to draw a line in cases of moderate drinking at what is termed "Anstie's" limit of daily allowance, "equivalent to one and a half ounces of absolute alcohol; three ounces of ardent spirits; two wine glasses of wine; one pint bottle of claret, champagne, or other light wine; three tumblerfuls of ale or porter; four or five tumblerfuls of ale or light beer." This is the limit of moderation in the use of spirits, beyond this there is risk of health and longevity, and this amount daily does not peril the health or life risk.

In face of the late advances in chemico-physiological science concerning the action of alcohol on the system such instructions are at least very startling. Nothing can be more theoretical, and assumptions, and flatly contradicted by both facts and experience. The attempt to map out lines of health and safety in the use of spirits is literally impossible. Many of the most incurable cases under my care have rarely exceeded one and a half ounces of absolute spirits daily. Many steady drinkers, who are incurable, seldom drink more, and in the majority of cases this is only an early stage of inebriety. Moderate drinking in this country is impossible, in the majority of cases. The excitement and revolutions of civilization, climate and strains, either precipitate the drinker into an inebriate of some sort, or end in acute organic disease. The moderation seen among the people of Europe is *exotic* in this country and only exists a short time, except as a marked exception to the rule. Boundary lines of moderation and health in the use of any form of spirits as a beverage is like drawing boundary lines in the twilight between night and day. From my experience I believe there are many inebriates who could pass a good physical examination and truthfully allege that they drank less per day than this limit of Anstie's.

Recently a gentleman who has had two attacks of alcoholism, with pronounced delirium and delusions, and has drunk for years at night at home, was examined and given a large policy. He answered truthfully that he drank moderately, at night, for years. This the examiner thought of little importance for the reason, probably, that he discovered no organic lesions to indicate any injury from this use of spirits. How far such errors of judgment are made in the well appointed companies is difficult to determine, but the assumption that any moderate use of spirits is free from peril, reflects on the business soundness and scientific accuracy of the management of the company. Another source of error is apparent in those companies, where the question of risks is left to the judgment of the medical examiner. As a rule, such examiners are among the best physicians in the country, and while they are thoroughly honest and conscientious, may not be

familiar with the latest teachings of science as to the action of alcohol on the system. The reason of this is, often such men are moderate or occasional users of spirits, and have formed fixed convictions concerning the use and effects of alcohol. Anstie's limit of health and moderation is to them a final truth because along the line of personal experience.

Not infrequently such men have been followers of the Todd and Bennett school, and their earlier impressions of the value of alcohol are more or less final. Should the medical examiner drink to excess occasionally, he reasons from his own experience, and readily concludes no harm can come from it, and that the will power is sufficient to restrain the use of spirits at any time. If such a man has drank to excess in early life, and had delirium, then abstained in a large degree, his judgment of the impaired health of persons in similar conditions will always be based on his own feelings, and that honestly and conscientiously. Such a man will readily pass an applicant who is a moderate drinker, or one who may have had delirium tremens, who gives no evidence of organic trouble. Such men never read any new literature on this subject; but consider it settled, and all new views fanatical and unworthy of confidence. I have seen such men who challenged me to prove the bad risk of a moderate or previously excessive user of spirits, because they exhibited no evidence of organic trouble. In the South this is more common because the use of spirits is more general; therefore, I conclude that medical men who use alcohol in moderation, or have used it in excess in the past, have "astigmatized judgment," and however acute they may be in other directions, are not, as a rule, capable of deciding the health risk of those who use spirits. The companies can not provide against this, and no exhaustive physical examination can do much to relieve the burdens of such dangerous risks.

To diverge a moment. It is the repetition of all psychological advances, that the errors concerning alcohol, and its action on the system, should "live so long and die so hard." Even today authors continue to repeat theories which never had any real scientific foundation, and even their seeming reality was a mere shadow, which any clear study would have dissipated. Most of the theories respecting alcohol have come down entirely on the respectability of authors, who have repeated them, and are accepted as facts unchallenged and unknown scientifically. While the real facts concerning the action of alcohol can all be put on a single printed page, the literature covers hundreds of volumes.

The question of the use and abuse of alcohol from the standpoint of life insurance should be no theory but one of unquestioned fact. Not opinions or theories, however eminent the authority

may be who endorses them, but facts and conclusions, sustained by every day's experience, and demonstrated with all the certainty of our present knowledge. From this point of view science has but one clear conclusion, namely, moderate drinking in any degree is perilous to health and longevity, and greatly increases the liability to disease. This is a fact that can be demonstrated by figures. If companies continue to issue policies on the lives of moderate drinkers, or persons who acknowledge the use of spirits occasionally or regularly, the rates should be made proportional to the risks. Thus a moderate drinker at twenty would have the same comparative longevity as a temperate man at fifty, and a moderate drinker at thirty would live as long as a temperate man at sixty. These figures bring out the fact that where both are free physically from traces of organic disease, the liability to disease and death in the moderate drinker, at a certain age would be increased to a certain definite rate, represented by age, and he should in strict justice pay for this, the same as hazardous occupations are charged increased rates. While the moderate drinker may not become an excessive user of spirits, there can be no question of his increased liability to disease, and diminished vital resources, also natural capacity to resist disease. In an epidemic the moderate and excessive users of spirits are the first to suffer and die. In accidents the spirit drinkers recover more slowly, have a longer convalescence, and are more like to die than temperate persons. The experience of the accident insurance companies abundantly confirm this statement. Hospital statistics in every large city show that beer and spirit drinkers who seem to be in excellent health and vigor have a limited degree of vital power and a special tendency to acute organic disease from slight exciting causes. They are unable to bear strains and shocks of any kind. They die from apparent inadequate causes, where others suffering in the same way recover.

Recently a moderate spirit drinker, from a fall fractured the femur. He died from shock and fever two weeks later. A beer drinker had his hand crushed and died from gangrene soon after. A spirit drinker suffered a slight exposure from an alarm of fire in his house, and died from pneumonia in a few days. Each of these cases carried life insurance policies and two of them had been insured recently as good risks and healthy cases. When temperate healthy men are insured in a company, and afterwards become inebriates, the policy should not be cancelled or invalidated, unless it can be shown that deception was used when the policy was made out. All such cases should be treated as those suffering from organic disease contracted after the policy was issued, and from conditions and exciting causes that could not have been anticipated when the insurance was placed.

Inebriety, like insanity or phthisis may appear at any time from the application of its peculiar exciting causes, and should be regarded as these diseases are. The theory of wilful voluntary contraction of this state has no support in the scientific history of cases. Recently a temperate and very reputable lawyer became an inebriate after fifty years of age. He had carried a large insurance policy for years and had been temperate up to the time of the drink impulse. One company cancelled his policy, another company more honorable continued its insurance on the promise of the policy holder and his friends, that every effort should be made for his recovery. He finally recovered and is in active life to-day. It is an injustice for a company to refuse to carry out a contract simply because a sudden peril comes to the life of the insured as in this case. A gentleman who had been temperate and well up to the sudden death of his wife, began to drink to great excess. He had fifty thousand on his life, and one large company made unseemly haste to cancel its policy. Later this man died of paralysis; his spirit drinking was only a symptom of this disease. An action was begun against this company and finally settled by a compromise. The failure of this company and its medical examiners to comprehend the first principles of science and equity in this case is a certain promise of their future failure. Another instance where a temperate man, after an attack of typhoid fever, developed acute dipsomania and two years later died of some obscure affection of the brain. Two out of three companies who held policies on his life annulled them, and the medical director of one company was emphatic in his opinion that this man was only giving way to a *crise* which he could stop any moment. This physician was himself a moderate drinker. The third company continued its policy, its management recognizing the purely physical nature of the case. Another question has come to me many times in the past few years. Where men who have drunk to great excess and reformed, for years living lives of strict sobriety, apply for life insurance. The physical examination reveals no organic disease and the question of the character of the risk is variously considered by medical examiners and companies. The facts which should govern in these cases are these: The disease of inebriety manifest in excessive use of spirits is thoroughly curable. The effects of the disease such as brain and nerve strain, with cardiac weakness, and lowered vitality, remain. The drink craze and impulse may die out, and the man be a total abstainer for life, but his longevity is impaired, his liability to disease is increased. Correct personal habits and careful hygienic living may do much to restore the lost capacities, and even a most minute physical examination will fail to find traces of this brain and nerve strain, yet they ex-

ist and any strain or exigencies will bring them out again. My advice in such cases is to issue a policy at such rates as are charged old men, along some approximate table of disease and mortality probabilities. The following case illustrates this: A man of good heredity was an inebriate during the war and for some time after, then reformed. Twenty years later he was refused a policy, from the fact that he had drank to excess for a period long ago. He was forty-eight years of age and free from apparent disease. I think a policy issued at the rates charged for temperate men of sixty-five or seventy would have been fair and just to all. I think no fact is clearer than this, the inebriate and moderate drinker, to a greater or less degree, have and are wasting their vital resources, and ageing themselves beyond all present indications. These injuries do not appear from any coarse physical examination, and when this fact is applied to excessive users of spirits it is not disputed, but it is not so clear in the case of moderated and occasional users of spirits. Yet it is the same only varying in degree. In many ways this fact is sustained by the experiences of the sick room and hospital, and should be fully recognized in practical life. Every advance in our knowledge of the action of alcohol on the brain and nerve centres brings additional confirmation.

Beyond all question there is much confusion in the theory and practice of both companies and medical examiners in this direction. An officer of a large company said that millions of dollars were lost every year from ignorance of the risks in these cases alone. Both companies who issue policies on moderate users of spirits and those who refuse to do so, are plunged into confusion of theory and practice, when these cases appear, they follow lines of action, that are both pecuniarily and morally of damage to both company and insured. From a scientific standpoint there are some general conclusions, which point to a way out of this difficulty, and promise if followed up to develop some new lines of facts of the greatest possible value.

1. The moderate or excessive user of spirits who can pass a good physical examination should be given a policy, on some basis proportional to the length of time he has drank, and the extent of his drinking. Comparative accurate tables of mortality could be formulated on these cases which would fairly represent the probable duration of life. This would necessitate an accurate study of a large number of such cases, the conclusions of which would be of the greatest value to both science and the companies.

2. Policy holders previously temperate, who become inebriates, should be the object of personal solicitude by the medical examiners, and required to use all rational means for recovery. Failure and neglect on the part of the friends to

use ordinary means for restoration should be the only reason for annulling the policy. This would also require accurate medical examination of such cases, and reveal lines of causes and conditions of disease which would enlarge the bounds of science, and bring a degree of accuracy where doubt and confusion exists at present.

3. Companies who refuse absolutely all policies on persons who have used spirits in the past, or do so at present, attempt too much, and fail in many cases. Such refusal should be based on the results of physical examination, and the question of the use of spirits should be regarded as an increased risk, requiring increased rates. This would prevent the deception and losses which follow, and enable the company to determine many of the questions now left to the changing judgment of its medical examiners.

4. The object of all companies, to minimize the uncertainty and risks of all policy holders, and make the question of the mortality of its insured a reasonable certainty, is a reality when the facts of alcoholic degeneration are studied above the level of opinion and theories. The greatest peril to life insurance to-day is the confusion of theory relating to the nature and action of alcohol. Every policy holder has to pay for this ignorance in the increased rates. The companies are periled, and a degree of uncertainty exists, which a larger and more accurate study of alcohol would remove. Companies whose managers and medical advisers are moderate drinkers, are on the road to failure. Companies who assume that this question is settled and the lines of health and disease can be mapped out, are failures already. Companies who regard this peril from alcohol as one requiring the most careful scientific study, and cautious application of the apparent facts of to day, will arrive at some rational lines of successful solution of the problem. Finally, the alcoholic question, from every point of view, demands a new and more exact study, to lift it out of the fogs and moss-covered superstitions of the centuries.

MONOMANIA.

Read before the Chicago Medical-Legal Society, December 6th, 1890.

BY HENRY M. LYMAN, M.D.,

PROFESSOR OF PRINCIPLES AND PRACTICE OF MEDICINE, RUSH MEDICAL COLLEGE, ETC., CHICAGO.

Monomania is a term that has long been in use in medicine, but the signification that has been attached to it is rather vague on the part of the general public, especially so in consequence of the fact that it is supposed to denote a form of insanity in which a person is perfectly sane and sound in mind and body on every subject but one, and upon that particular subject he entertains some irrational ideas that dominate his thoughts. That is the popular idea of mono-

mania, but it is well known by intelligent physicians and alienists who have given much time to the study of these cases that there is no such thing possible as a person perfectly sound in mind and body and sane upon all subjects but one. It is recognized by alienists that cases which have been called monomania are persons who are really insane and who are unsound in mind and body, for the one implies the other, and that their insanity and their unsoundness of mind is more especially conspicuous in one or more directions than in others. It is rather an emphatic form of insanity in a particular direction and about particular subjects, than an instance of simple delusion in a sound mind and body. The tendency is to limit still further this term and to restrict the idea that is conveyed by the word "monomania" to a particular class of patients; not characterizing by that term persons who manifest a particular delusion, or system of delusions that are more prominent in certain directions than in others, but restricting the word monomania to those persons, who manifest an unsound mind—unsound as a consequence of hereditary causes—and unsound in a way that produces delusions and false reasoning about certain topics. And in order to do away with the confusion which attaches to the use of the word "monomania," alienists now are in favor of giving it up and of substituting a term that has been long used in medicine, though not made conspicuous in alienistic science until lately; that is the term "paranoia."

The term "paranoia" signifies a disturbance of the mind, and it is employed to signify a consistent derangement regarding particular subjects. Within the last few years there has been a great deal of writing and discussion, and there has developed a good deal of difference among authors as to the restrictions that should attach to the term "paranoia." This difference of opinion, however, seems to grow principally from differences of opinion as to whether there should be a limitation of the use of this term to cases that are congenitally defective, or whether there should be included together with the congenitally defective patients, those that have become defective as a consequence of other diseases of the brain. This opens a very wide door for difference of opinion and discussion as to what shall be the true signification of the term "paranoia;" but you will find a disposition to classify the cases that used to be called monomania into two great categories: those that are congenitally defective, and those that have become defective as a consequence of cerebral disease, or through other diseases than insanity, operating upon the brain in such a way as to produce insane ideas. The great characteristic of the majority of cases of paranoia is delusion. English authors still incline to the use of the term delusional insanity; and a very large number of cases can be assigned to this class, because

there are really very few patients who do not at one time or another exhibit some form of delusion. Nevertheless, I think we are now in a position to restrict the use of the term "paranoia" to persons who are congenitally defective, and who are dominated by one or more systematized delusions, in such a way that their reasoning faculties remain in a large measure intact and their general health unimpaired to any serious degree; and the principal difficulty in their cases lying in the fact that they reason wrongly from certain data which are presented to their hampered minds.

When we proceed further to examine these cases, we find that they rank themselves into sub-varieties. We will say, there is the genus-paranoia; then there are species of paranoia in which certain forms of delusion are most prominent; for example, there are patients dominated by delusions of an expansive character, the delusions which they entertain are those that are frequently termed in medicine "grand delusions." Then, there is another class of patients in whom the delusions are of a depressive character, these approach in many respects the delusions of melancholia; then, there are cases in which the patient takes on the characteristics of both these classes and is dominated by delusions of an expansive character, which are also of a somewhat depressing nature. He is dominated by the idea of persecution, believes that people are in a conspiracy against him, and that his life is being ruined by such persecution. These patients sometimes turn upon their supposed enemies and instead of remaining persecuted they become persecutors. They fancy that they have a mission to set wrongs right and to pursue evil doers, and sometimes they do a great deal of mischief in society. Then again, the delusions may assume an emotional character that is usually either of a religious or of an erotic nature. There are many conspicuous examples in the history of the world of patients whose delusions have been of a grand and noble character, tinged strongly with a religious coloring; perhaps with the consequence that they have played a very important part in the history of the world as religious leaders, as founders of schools of thought, as authors of schemes, for the regeneration and elevation of humanity. Indeed it seems to me rather difficult sometimes to draw the line between a paranoiac of this character and an individual of sound mind and body who is dominated by benevolent impulses, not of unsound character. Again, there are those whose delusions take an erotic turn, and who are impelled by certain erotic notions that do not always assume the form of obscenity or unchastity, but show a preponderance of sexual passion and inclination in some form or other. It is in this way that the disease usually manifests itself. Were time sufficient it would be easy to illustrate the

different forms of paranoia with which we meet, but I will only hint at two or three cases. I think they are cases with which my friends, Dr. Brower and Dr. Church are very familiar, and about which they probably know more than I do, as they have had an opportunity of becoming more fully acquainted with them, and I hope they will give us some particulars with regard to them.

I will allude in the first place to the case of the young man, who on one occasion in this city assaulted a very distinguished actor in the theater, firing a pistol at him from the gallery with the view of committing murder, under the influence of the insane delusion that he was the son of the actor, that he was a gifted tragedian himself, though not recognized by the world, that his mother had been ruined by this actor, and it was his mission, not only to assert his own dignity and superiority as an actor, but to bring to justice the aggressor upon the rights of his family. I think this was a very good illustration of the form of paranoia we sometimes meet, in which there are what we call "grand delusions" of superiority and greatness; and with that, as in this case, may be joined a disposition to right wrongs.

There was another noted case, which I think Dr. Church had under his observation at Elgin. It was the case of Joel Henry Wells, with whose history I am not well acquainted, that is, I am not acquainted with his family history and the hereditary influences that were brought into action in his case. He was a man who was apparently of sound mind and body when I saw him, and evidently gifted with large reasoning powers and great acuteness of observation, adroitness and ingenuity; but, nevertheless, was dominated by a most singular delusion of the grand type. He was really the son of a modest unassuming farmer, but he believed that he was no such person, but the son of a foreign nobleman, and he constructed a most intricate and complicated history to account for all his course of action during a long period of time.

With regard to these delusions there is another point I must mention, that they are characterized by remarkable consistency. Delusions are exceedingly common among insane people, but as a rule their delusions are not homogenous. They arise as the clouds go across the sky, assuming all sorts of shapes and forms, and vanishing as quickly, but it is not so with the delusions of the paranoiac. He starts out with some dominating delusion, and as that delusion proceeds it assumes definite shape and form, and the actions that are based upon that delusion are as consistent as are the daily actions of a person of a sound mind; so that they differ entirely in this characteristic from the ordinary delusions of mania or melancholia, or any other variety of insanity. To distinguish them from the shifting half-formed and impotent

delusions of ordinary insanity they are generally spoken of as systematized delusions. I think Dr. Church can give us in the history of some of his patients very interesting examples of the consistent form which the delusion will take in the brain of the paranoiac patient.

A number of years ago I was visited by a family from the country, respectable people, the father, mother, and a young man of about 22 years of age. The young man appeared perfectly well, there seemed to be nothing whatever the matter with him. I conversed with him and he talked like any other person in a perfectly reasonable way. I could discover in his conversation no evidence of a disordered mind. Why had they come to see me? Conversation with the parents revealed the fact that he was laboring under the delusion that they had become Mormons and were carrying on, as he said, Mormon practices in their house and the neighborhood. Expostulation on the part of his parents and friends produced little or no effect. He would acquiesce in everything that was said, but in a little time his acquiescence would be forgotten entirely, and the delusion would press upon him again. He went to the sheriff of the County, and talked with him about the steps that would be necessary for breaking up this Mormon nest in the household. When I was informed of this delusion I talked with him about it, and asked him if it was true; he said he supposed it was all a mistake, he had thought it was so, but he didn't think it was so now, and probably he was mistaken; he was willing to admit that he had been the victim of a delusion. I cautioned his parents about his condition, told them what it probably meant and what might be the outcome, warned them of the possible consequences of living in such a way; and advised them by all means to have the young man placed in safety. They went away and I heard nothing more of the matter for a considerable time. One day I picked up a paper and read the account of a murder which had taken place in that locality, and learned that this young man was the murderer; he had murdered his mother. He was out at work in the field when he made some excuse, went back to the house, took up a gun and shot his mother dead. The delusion had come upon him in full force, and under its influence he had gone to work to do justice upon his supposed Mormon mother. That is the way with these paranoiacs, they may appear perfectly rational, and may talk in a way to deceive the very elect.

I remember on a notable occasion in the case of Joel Henry Wells, of whom I spoke a little while ago, he was brought into court, and members of his family came to testify before the court that he was a perfectly sane man; but before many days they all admitted that they had been deceived and that he was insane. So these persons may deceive the very elect in a casual conversation. It

may require considerable ingenuity and an extended acquaintance with a patient to detect the existence of a delusion; and when that delusion is presented it will be found so plausible, so consistent in all its parts, that unless you have information in regard to the individual and his surroundings you may be deceived. In the instance of the man just referred to, when he took the stand and told his story he told it in such a consistent, interesting manner that a bystander, unless he knew some reason for disbelieving the narrative, would accept it; the Judge himself was completely puzzled. At last the veracity and probability of the story turned entirely upon the determination of the actual fact of an incident that he related. He told of a marriage which had taken place in a certain church, in a certain city and at a certain time. It happened to be a Roman Catholic church where it is customary to keep a record of such events. The judge at once recognized the possibility of testing the truth of this apparently plausible narrative, so he sent to the church indicated for information as to the truth or falsity of this statement, whether such a marriage had taken place or not. Word came back that no such marriage had ever taken place in that church, and this showed at once that the whole story was a delusion; yet it was so consistent in all its parts that without a knowledge of the history of the patient it would have been impossible for a stranger to detect the falsity of the narrative or the fact of the delusion.

I will not take up more time as Dr. Brower and Dr. Church can undoubtedly contribute a great deal more on this subject than I can.

(For discussion, see Society Proceedings.)

RECENT MEDICAL CASES IN THE COURTS.

BY HENRY A. RILEY, ESQ.,
OF NEW YORK CITY.

RECENT LEGISLATION TO REFORM CRIMINALS.

A summary of legislation concerning the public health and the public morals was published not long since, covering the statutes enacted in the various States during the previous twelve months, and that portion relating to crime is of general interest. The writer says: "the statutes of several States reflect the humane and growing sentiment that the punishment of criminals should contemplate, and as far as possible provide for their reformation."

Ohio authorizes general, or what are known as intermediate sentences for all persons for the first time convicted of felony below murder in the second degree, the board of managers of the penitentiary being authorized to terminate the imprisonment of any person so sentenced in case of good

conduct, at not less than the minimum of imprisonment provided by law, and if sentenced for more than one successive term for separate offenses, to remit the succeeding term or terms at the close of the first. Similar Acts were passed by New York and Michigan in 1889, but with further provision for allowing prisoners so sentenced to go at large on parole, subject to be retaken and imprisoned for violating its conditions.

A Kentucky statute limits the number of penitentiary prisoners who may be paroled in any one year to five per cent. An Iowa statute provides for shortening the time of convicts as a reward for good conduct, at the rate of one month for the first year and an additional month for succeeding years until one half is remitted, but such "good time" to be forfeited for misconduct or attempted escape; and another Act of that State appropriates \$1000 to be expended by the Iowa Prisoners Aid Association in helping discharged convicts to an honest life.

EXTRADITION AND THE NIHILIST PADLEWSKI.

The murder of General Seliveskoff at Paris by the Nihilist Padlewski has caused renewed attention to be paid to extradition laws, and some of the Governments of Europe have made great efforts to secure legislation more suited to the free extradition of persons charged with offences more or less political.

Considerable interest has been felt in the position of Switzerland, which country has long been known as a safe asylum for persons charged with political offenses. It has been said that a recent law was a concession to the reactionary party and would permit the extradition of such persons.

The text of the law does not seem to warrant such a statement, and in reality maintains the traditional position of Switzerland.

It says: "Extradition shall not be granted for political crimes and misdemeanors. Still, whenever the accused person shall plead political motives or aims, extradition shall be granted if the act for which it is demanded is one of the graver crimes or misdemeanors under the common law."

"The Federal tribunal shall examine the facts and decide upon the nature of the act. Whenever extradition shall have been granted, the Federal Council shall demand that the person to be extradited shall be neither charged with nor punished for political crime, and also the punishment shall not be made the more severe because some political motive or aim might be laid to the charge of the accused person."

A DEFINITION OF DELIRIUM TREMENS.

In a recent case in Indiana an insurance policy freed the company from liability where the assured "shall become so far intemperate as to impair his health seriously or permanently or induce delirium tremens," and the Court held that delir-

ium tremens was "that diseased condition of the brain said to be produced by the excessive and prolonged use of spirituous liquors."

The insurance company objected to this definition of the disease but the Appellate Court was of the opinion that it was correct and as favorable to the company as could be asked for.

PHYSICIANS ON A STRIKE.

Many of the physicians of Dutchess Co., New York, have inaugurated a strike against the Board of Supervisors. They have sent in a petition very largely signed in which they say that they believe \$10 to be a just and fair charge for an examination of a dead body before a coroner; \$25 a just charge for ordinary autopsical examinations, and \$10 a just charge for an ordinary examination in lunacy.

They further declare: "We do hereby agree not to perform the duties of coroner's physician or as examiner in lunacy for a less sum than stated; and we would respectfully ask your Board to fix the above charges as legitimate rates."

WHEN A HOUSE IS UNTENANTABLE.

The ordinary rule in house tenancy is that the lessee is liable for rent even though the building become rickety and poor. In some of the States, however, as in New York, the lessee is freed from his obligation if the property becomes "untenantable and unfit for occupancy." This limitation naturally comes up frequently for construction in disputes between landlord and tenant, and a recent decision shows certainly that the tenant in one case was entitled to abandon his lease. It appeared from the evidence that the building was shaken by repeated explosions, which caused the walls and ceilings to crack, the plaster to fall, clocks to stop; that the building was declared by the public authorities to be unsafe and dangerous, and that the rooms were at times so filled with coal gas and smoke as to make the inmates sick. The landlord ventured the cheerful opinion that the explosions were the result of dynamite being exploded somewhere in the house. The Court decided that the tenant was having a hard time and that he was constructively evicted and need not pay rent. It must not be understood however, that he could continue to occupy the premises and not pay rent. He must go out if he did not want to pay rent.

HYPNOTISM IN CINCINNATI.

The Common Council of Cincinnati has just passed an ordinance making it a misdemeanor to give hypnotic exhibitions. Dr. J. W. Prendergast, Health Officer of that city, is of the opinion that hypnotism, when applied indiscriminately, is injurious, as it affects the mental health of the subject, and recommended the enactment of the ordinance. A lecturer on hypnotism was refused a license and obliged to leave the city.

HEALTH ORDINANCES IN THE SOUTH.

Not long since a Southern town, desirous to secure the title and emoluments of a health resort, passed an ordinance declaring that no land within the city limits exceeding an eighth of an acre should be cultivated by any one person except for flower gardens, the grape, and trees of all kinds, and absolutely forbidding the cultivation of rice under any circumstances. This ordinance came before the State Supreme Court for review and was held valid under the general power held by all communities to legislate for the health of the town. It is evident that the South is bound to secure the reputation of being healthy even if food has to be imported from other sections, on account of the non cultivation of the soil.

FEDERAL LAWS ON IMMIGRATION.

The subject of controlling undesirable legislation will occupy considerable attention at the present session of Congress, and one of the main objects will be to amend the laws so as to prevent paupers, criminals and insane immigrants from entering the United States by way of Canada. A bill has just been reported in the House of Representatives on the subject, but as it contains no reference to Canada will require amendment. One section of the bill imposes a fine of \$1000 or imprisonment on any person who brings into the country an alien not entitled to land. This requires almost supernatural knowledge on the part of the Captains of transatlantic steamers and will no doubt have to be changed.

THE CLINIC.

LARYNGEAL PAPILLOMATA IN A CHILD THREE YEARS OF AGE; ENDO- LARYNGEAL REMOVAL.

A Clinical Lecture in the Rush Medical College, Chicago, Oct., 1890.

BY E. FLETCHER INGALS, A.M., M.D.,
PROFESSOR OF LARYNGOLOGY.

Gentlemen: I have to show you to-day a little boy who was recently sent to me from New Mexico because of aphonia and difficulty in respiration. The mother gives me the following history: The boy, who is now 3 years of age, has never been able to speak aloud, and was always troubled with difficulty in breathing whenever he took cold, indeed there has been something peculiar in his respiration ever since birth. When he was 2 years of age the parents noticed enlarged tonsils, which it was thought might be the cause of his difficulty in breathing. He was then taken to a physician who gave him some local and internal treatment, with the hope of reducing the size of these glands. About last

Christmas his breathing became much worse, and continued to grow more and more difficult until about the middle of February, when he was taken with an acute inflammation of the larynx, the result of a cold, which was attended by the symptoms of croup. For this he was given emetics that caused the vomiting of a considerable amount of mucus, which seemed to relieve him for the time being. But about a week later tracheotomy became necessary to prevent suffocation. Shortly afterward it was found that he was unable to breathe at all through the larynx, and about the middle of March and extending over a period of six weeks, several attempts were made by the local physicians to relieve the obstruction, but without any very satisfactory results. He was finally brought to my office during my absence from the city and was examined by my assistant, Dr. J. E. Rhodes, who told me that by pressing the tongue down firmly he was enabled to see a portion of the tumor rising above the tip of the epiglottis. A few days later I saw the child for the first time; his experiences had been such that he began to cry and fight the moment he was brought into my consultation room, and therefore I found it useless to try to inspect the larynx. By closing the tracheal tube I found that no air could pass through the larynx. I placed a gag in the child's mouth and passed my forefinger behind the epiglottis, where I could distinctly feel a large mass completely filling the vestibule of the larynx. This was soft, had a granular or uneven surface, and felt in all respects like a papillary tumor.

It was impossible to remove any portion of this tumor with the finger nail, therefore I selected a pair of short, strong laryngeal forceps with spoon-shaped cutting blades, which I passed into the larynx, guided by the index finger of my left hand. With these I succeeded in removing at one bite a mass of the tumor as large as a filbert. Introducing the forceps two or three times more I removed other pieces of this growth, so as to practically free the vestibule of the larynx. By this time there was so much blood, and the child was so exhausted from his continual struggle that I postponed further operation until another sitting.

Subsequently with forceps cutting antero-posteriorly or laterally I removed piece after piece until the vestibule of the larynx appeared free. I then passed the forceps through the glottis and removed several masses from below the cords, thus at four or five sittings the tumor was apparently entirely removed, but still the boy could not breathe when the tracheal canula was closed. This was due, partially at least, to granulation tissue springing from just above the tracheal canula. I removed this, but when the patient returned some days later I found him unable to breathe through the mouth, the glottis being ap-

parently closed by adhesions of the vocal cords. With my finger in the larynx as a guide I then forced between the cords a forceps opening antero-posteriorly; then holding the blades open I withdrew the forceps, thus dilating the glottis throughout its entire length. Four or five days later the condition had returned and the same operation was repeated. At a recent sitting I attempted to place an intubation tube in the larynx, which I hoped to leave until healing of the cords had occurred, but the opening in the trachea had been made so high up that, although the tube had been shortened for the purpose, it was impossible to introduce it without striking the tracheal canula before its head had reached the vestibule of the larynx, therefore I was obliged to abandon the plan.

All varieties of abnormal growths have been found in the larynx, but the most frequent of these are papillary tumors, about 75 per cent; next to these come the fibrous, and next to these the fibro-cellular growths, and after these are scattering cases of adenoma, angioma and sarcoma. In most of the cases, that we can examine laryngoscopically, the tissues are found congested, and tumor springing from the edges or upper surface of the vocal cords, but sometimes they grow from the under surface near the anterior commissure, or from the ventricular bands. In the case which I have shown you the tumor seemed to grow not only from the epiglottis, ventricular bands, and edges of the cords, but also from the sub-glottic portion of the larynx. Such growths are generally attributed to repeated or continued hyperemia of the larynx, and sometimes they result from the laryngitis following measles, scarlet fever, croup or diphtheria. Rarely they are congenital, as seems to have been the case in this patient.

The usual symptoms of laryngeal tumors are dyspnea, dysphonia or aphonia, dysphagia, and occasionally pain. These of course vary with the size and location of the growth. Cough is occasionally present, but is not apt to be troublesome unless the tumor is large and involves the epiglottis, or unless it bleeds easily. When present the cough is frequently of a croupy character, as was observed in the case which I have shown you. Dysphonia or aphonia is one of the most common symptoms. It was present with this patient from the very beginning, and was the first symptom to attract the parents' attention. It depends upon the position of the growth and the amount of concurrent inflammation, and will therefore vary from time to time. It is sometimes intermittent, because of changes in the inflammation or the position of the tumor. Dysphagia is comparatively frequent in malignant tumors of the larynx, but does not often occur with benign growths excepting when the tumor involves the epiglottis or the posterior laryngeal

wall. Pain is not often present excepting with malignant growths, though a sensation as of a foreign body or a slight uneasiness in the throat is not uncommon, especially upon deglutition.

Diagnosis.—Upon a satisfactory laryngoscopic examination of the larynx these tumors may be readily detected, though it is impossible in all cases to be certain of their true character until portions have been subjected to microscopic examination, and even then the diagnosis may remain in doubt, for sometimes laryngeal growths which present a malignant histological appearance may have a benign history from beginning to end. In very young children, however, satisfactory laryngoscopy is seldom attained, and then the examination must be made, as in this case, by palpation. However, even in children a good view of the larynx may sometimes be secured if the tongue is pressed downward and at the same time drawn forward by Mount Bleyer's depressor, as recommended by that gentleman in forcible laryngoscopy during diphtheritic croup.

The affections which are most liable to be mistaken for benign growths of the larynx are syphilitic or tubercular laryngitis, and malignant tumors. None of these are likely to occur in young children, though the possibility of syphilitic laryngitis must not be overlooked and critical inquiry must be made into the history before an accurate diagnosis can be arrived at. Specific condylomata, although rare, may possibly be mistaken for a tumor of the larynx. These consist of slightly raised irregular prominences of a whitish color situated on the congested mucous membrane. They usually occur within five or six weeks after inoculation and rapidly disappear under anti syphilitic treatment and the local application of astringents, whereas a laryngeal tumor is little affected by these measures. Tubercular laryngitis is attended by swelling, ulceration, severe pain, and grave constitutional symptoms which are not present in the cases under consideration.

Malignant tumors of the larynx may not be easily distinguished at first, but may be suspected when there is decided localized congestion and the growth appears to involve the whole thickness of the mucous membrane, and the submucous tissues. Later they are characterized by thickening and distortion of the parts, more or less pain, and finally before many months by marked cachexia and constitutional symptoms, in which respects they differ much from most benign growths.

Papillomata are usually located on the upper surface or the free margin of the vocal cords, but they may occur in other portions of the larynx, as in the case that I have shown you. They are generally of a light pink color, but may be white or even red. They usually have an irregular cauliflower or raspberry like surface, and may

vary in size from a few millimetres in diameter to a mass large enough to completely occlude the larynx, as in the child I have presented to-day. Though sometimes pedunculated they usually spring from a broad base and several tumors may exist in the same case. These tumors are soft and may be readily torn or crushed with forceps, as in this patient.

Fibrous growths are small, round and firm, and could scarcely be confounded with papillary tumors. Other varieties of intra-laryngeal growths are so uncommon that in case of a child like this they could hardly affect the question of diagnosis.

Prognosis.—The tendency of these growths is to steadily progress until the voice is lost and respiration more or less interfered with. In children they are very likely sooner or later to cause suffocation unless efficient treatment is adopted.

Treatment.—Although these tumors have been known to disappear without operative procedure, there is no reason to believe that any internal medication is of any value in their reduction, and it is doubtful whether the local application of astringents has any influence upon their progress. Therefore the only treatment to be recommended is the removal of the growth by suitable instruments. Intubation as recommended by Dr. Joseph O'Dwyer, for diphtheritic croup, has been practiced with some success in a few cases for the relief of papillary growths in the larynx, but is a method of treatment that can hardly prove curative in the majority of cases.

Various tube forceps have been recommended for removing these growths, but I prefer common forceps bent to suit the larynx, opening antero-posteriorly or laterally, with crushing or cutting blades according to the nature of the growth. These are commonly known as Mackenzie's forceps, various modifications of which I have had made to suit special cases. Guillotines and snares have also been recommended, and they are admirably suited to certain cases. Voltolini's method of rubbing the growth firmly with a sponge attached to a suitable staff will be found effectual in some cases, and is especially to be recommended in young children, when the growths are soft. The galvanocautery has also been employed for the destruction of these neoplasms, but it should never be used excepting by those whose hands are steady and experience large. When it is used, the platinum point should be made of fine wire which will heat or cool very quickly, so that other portions of the larynx will not be injured. Chemical caustics are also recommended for the destruction of these growths; the ones most frequently employed being the nitrate of silver and chromic acid, either of which may be fused upon a probe so that there is no danger of the caustic dropping into the trachea. Nitrate of silver I have never found of much value excepting for cauterizing the

base after a tumor has been removed, but chromic acid, used in small quantities, is very efficient. In applying it I fuse a small portion of the acid, amounting to not more than twice the bulk of an ordinary pin's head, upon the end of an aluminium probe. I slip down over this a short section of small rubber tubing, which is prevented from falling off by a silk thread attached to it and wound about the probe and brought up to the handle. Where I wish to cauterize with the end of the probe the tubing is passed down slightly beyond it, and is crowded back by slight pressure as the probe touches the part to be cauterized. When I wish to cauterize with the side of the end of the probe, a small piece is cut out of the rubber tubing in the proper locality. The larynx is very apt to contract immediately after the growth is touched, but this section of rubber tubing prevents the acid from being smeared upon other parts as the probe is withdrawn. In using forceps they should be applied accurately to the growth by the aid of the throat mirror whenever this is possible. But, as in the case which I have shown you, it will sometimes answer to apply them guided only by the finger and a knowledge of the condition of the parts. General anaesthesia is not usually practicable in operations of this kind, though it might sometimes be admissible in young children when tracheotomy has first been performed. Ordinarily local anaesthesia should be induced by the application of a 10 to 25 per cent. solution of cocaine, before an operation of this kind is attempted, but in children great care should be exercised that too much of the drug is not used.

Whatever operation is performed, cold applications to the neck should be directed for twelve or thirty-six hours afterward in case any soreness results, and the operation should not be repeated until three or four days after all tenderness which may have been caused by the first operation has disappeared. The patient should be cautioned to use the voice as little as possible until all congestion has subsided. The application of astringent sprays daily or three times a week will aid in the reduction of the inflammation.

The indications for extra-laryngeal operations consist of large, dense, or inaccessible growth or growths in young children where the inter-laryngeal method cannot be practiced. But this method should not be tried until a skilful laryngologist has failed to remove the growth by the natural passage and should never be tried simply for the relief of the voice, but only when the growth endangers life, because laryngotomy is itself a positive danger to life and the operation very seldom restores the voice, besides, recurrence is quite as common after operation done in this way as after the laryngeal method. Laryngeal growths have occasionally been removed in children by the finger-nail alone, but in cases where all or a part of

the growth is attached low down it would be impossible to accomplish this result without the aid of forceps. In this patient I believe that all of the tumor has been removed, and it is my purpose to-day to take out the tracheotomy tube and to insert an O'Dwyer's intubation tube which will be allowed to remain for a few days until the parts appear to have healed. The intubation you will observe is performed the same as for diphtheritic croup.

Upon withdrawing the tracheotomy tube I now find a mass of granulation tissue above it which I will remove by means of a punch-like cutting forceps which I had made for a similar case. It is very difficult to remove these growths with ordinary forceps as the granulations slip away from the blade into the trachea upon every attempt to seize them. Having removed the granulation mass I will now introduce into the larynx a pair of ordinary laryngeal forceps in order to ascertain whether the glottis is patent; I find this to be the case and you may readily see the end of the forceps through the tracheal opening. I will now introduce one of the smaller sized Schroetter's dilators, a No. 5. This is large enough to fill the trachea and will therefore crowd down to the tracheal opening any granulations above it. I find the passages perfectly clear—the child now breathes easily—I will now introduce the O'Dwyer's tube suited for a child three or four years of age. This done, the head of the tube rests in the larynx, and the body may be seen through the tracheal opening. I now cut and withdraw the string, and the tube is left in the larynx, where it will remain until the tracheal opening has closed.

I regret that the original opening had not been made farther below the larynx, as that would have allowed us to introduce the intubation tube and leave it until we were assured the larynx was in a healthy condition before removing the tracheotomy canula, as it is if our present plan does not succeed it will be necessary to again open the trachea. During the next few days this child may be fed upon soft solids or fluids, but fluids must always be given with the body in a reclining position of about forty-five degrees, the head being lowest, so that the liquid cannot run into the trachea.

NOTE.—The intubation tube was removed seven days later. The tracheal wound had then been closed for six days and the child breathed perfectly after the laryngeal tube had been taken out. He had never spoken aloud in his life and made no effort to do so for about three weeks, but the whisper grew louder after a few days.

December 21, at the end of six weeks, the tumor was again found to be growing—portions were removed and an intubation tube inserted but, finally, a mass which grew from the under surface of the epiglottis, and which could not be

removed excepting with the curette, necessitated the reintroduction of the tracheal canula, which was put in to-day lower down so that it will not interfere with a short laryngeal tube, which will be needed after future operations to prevent adhesions of the cords.

Two days later a severe bronchitis developed, which proved fatal in about ninety-six hours. No post-mortem could be obtained.

MEDICAL PROGRESS.

Therapeutics and Pharmacology.

TREATMENT OF HIGH TEMPERATURE IN TYPHOID FEVER AND PHthisIS PULMONUM WITH SMALL FREQUENTLY REPEATED DOSES OF ANTIFEBRIN.—DR. AUGUST FAVRAT has treated a large number of cases in the wards of Professor Sahli, in Berne, with small, frequently repeated doses of antifebrin (*Deut. Archiv. f. klin. Med.*, Hft. 6, 511). He is strongly in favor of antipyretic treatment, as it greatly increases the comfort of the patient, and, by lessening metabolism, tends to husband the strength. The author points out at some length that most antipyretics are depressing, and that many of the newer ones are used rashly in practice, before we are thoroughly acquainted with their dangers, their doses, and the most effective ways of exhibiting them. When one reflects how long it has taken us to become even imperfectly versed in the possibilities to be attained with digitalis, opium, etc., we must conclude that new medicines are too lightly introduced, and in many cases too lightly cast aside. These considerations, and the fact that antifebrin, although a sure and active antipyretic, has certain drawbacks, such as the production of collapse, cyanosis, etc., have induced Professor Sahli and the author to try if they could not obtain the antipyretic action and at the same time avoid these drawbacks by giving the medicine in small repeated doses, instead of in a single large dose, as is customary. The advantages of such a plan are obvious, as any unpleasant effects may be at once observed and the medicine stopped before serious harm has been done. Antifebrin acts rapidly, and is therefore specially suited for exhibition in small repeated doses, whereas a slowly acting antipyretic, such as quinine, either has no action in small doses, or causes a cumulative action after several doses have been given, thus losing the advantages to be derived from a divided dosage. In typhoid fever antifebrin was given in 1 to 1½ grain doses hourly in four cases. In no case was more than 20 grains given during the twenty-four hours. The action was satisfactory, and in all cases the temperature fell more markedly the higher it was. In seven cases

in which similar doses were given every two hours the reduction of temperature was scarcely sufficient. When the morning temperature was not over 101.5° F., however, a two hourly dose was found quite sufficient (four cases). Similar doses kept the temperature about normal in cases of phthisis. Neither in typhoid fever nor in phthisis did antifebrin exert any specific action on the course or duration of the disease. In all these cases antifebrin was well borne; a gentle antipyretic effect was maintained; in several cases sweating was present, but only in two was there the least sign of cyanosis or rigors. In no case was the patient ever much disturbed, and there were never any alarming symptoms. In conclusion the author gives a warning against the use of large doses, 3 grains being reckoned as such. Although much larger amounts are often well borne, yet in certain cases fatal results have ensued. A number of such cases are cited.—*Brit. Med. Journal*.

PILOCARPIN IN SKIN DISEASES—DR. KLOTZ (*Mon. of Cut. and Genito-Urin. Dis.*, November, 1890) treated cases of eczema with daily hypodermic injections of ten to fifteen drops of 1 per cent. solution of muriate of pilocarpin. The first case was that of a man, aged 28, who had suffered for several years from eczema. The skin showed no great infiltration in any part of the body, but was dry, hard, resistant, and slightly scaling. After the first injections the reaction was very slight, moderate moisture appearing on some of the less affected portions, but it generally became more distinct, and after about twelve injections a general secretion of sweat was produced. The patient left the hospital after the seventeenth injection. The scales had almost entirely disappeared, the skin was much softer and more pliable, and showed "more natural turgor and elasticity," itching having become very insignificant. The second patient, aged 21, suffered from eczema squamosum and rimosum of both palms, which were covered with a very hard and thick horny skin divided by numerous cracks. Other treatment having failed, daily injections of pilocarpin were given, the patient at that time being unable to bend or close his fingers. After nineteen injections perspiration, which had previously appeared on the forearms, wrists, and backs of the hands, now appeared for the first time on the palms. On June 1st the horny condition of the surface of the palms had entirely disappeared, the skin looked natural, showed all the ridges and indentations of the surface, and was soft and pliable, and the patient could move and close the fingers without pain or difficulty. A third patient suffered from a general papular eczema, which was attended with considerable thickening on the flexor aspects of both elbows. Over the chest and abdomen and in a milder degree on the extremities the skin

was hard, dry, slightly scaling, dark brown in color, with numerous small hard papules of a somewhat lighter color. The patient left the hospital after eight injections, at which time the skin had lost a great deal of the dryness and hardness, the papules had been greatly reduced in size, and the itching had almost disappeared. In the discussion at the meeting of the American Dermatological Association which followed the reading of this paper Dr. Hardaway stated that his experience of this treatment in ichthyosis, eczema, alopecia, and pruritus was not such as to lead him to continue it.

INJECTIONS OF PYOKTANIN IN CYSTITIS.—DR. LEON NENCKI, of Warsaw, reports (*Gazeta Lekarska*, No. 32, 1890, p. 642) four cases of exceedingly obstinate chronic cystitis (three of gonorrhoeal, one of rheumatic origin), in which, after ordinary measures had completely failed, the injection of a 1 in 1,000 and 1 in 500 solution of blue pyoktanin, repeated twice daily, was followed by cure in from ten to fourteen days. In every one of the cases, a very marked amelioration (decrease in turbidity of the urine, disappearance of alkaline reaction and pain, etc.), took place in a couple of days after the beginning of the treatment.

Medicine.

POINTS IN THE DIETETIC MANAGEMENT OF CHILDREN.—RACHFORD formulates the following rules, which will aid us very much in selecting a diet when it becomes advisable to discontinue milk temporarily: 1. Avoid albuminous food, *a*, when marked constitutional symptoms are present; *b*, when in doubt as to the character of the fermentation causing the disease; *c*, when the stools are putrid; *d*, when the stools contain mucus and blood; *e*, when the nausea is constant and not relieved by vomiting. 2. Avoid carbohydrates as a food, *a*, when there are no marked constitutional symptoms present, and the stools are continuously acid; *b*, when there is much flatulency, pain or urticaria. 3. When the albumens are to be avoided, the carbohydrates are, as a rule, indicated; and when the carbohydrates are to be avoided, the albumens are, as a rule, indicated. 4. Give foods, such as cream, beef-broths and whisky, *a*, when the foods prescribed according to the above rules disagree; *b*, during the first twenty-four hours in severe acute cases; *c*, when in doubt as to the character of the food indicated. —*Archives of Pediatrics*.

TREATMENT OF ACUTE TONSILLITIS.—SURGEON HEHIR (*Indian Med. Gazette*, November, 1890), in cases of acute tonsillitis recommends the administration of pilocarpine to relieve the distress caused by the accumulation of tenacious pharyngeal mucus. One-eighth of a gr. in a teaspoonful of water every two hours, or $\frac{1}{10}$ gr. hy-

podermically every four hours, until slight salivation is produced, is sufficient. Locally he uses repeated poultices and constant steaming by means of boiling water near the patient's head. Internally, tartar emetic in doses of $\frac{1}{4}$ gr. to adults every two hours has given him more uniformly good results than any other drug, not excepting sodium salicylate. If any depression follows the use of the tartar emetic, which is unusual, ammonium carbonate or strophanthus may be given. Of stimulants he thinks port wine the best, and believes that it has some local beneficial action upon the inflamed tonsils. Guaiac mixture is sometimes very useful in relieving the shooting pain often complained of during the act of swallowing. It is usually good practice to begin treatment by the administration of a mercurial followed by a saline purge. Dr. Hehir has repeatedly seen marked relief follow a simple puncture or small incision of the tonsil, and this should be done whenever the gland is greatly swollen. It is much preferable to the use of leeches in the submaxillary region. He believes that strong astringent gargles are of very little use during the acute stage, but that tepid antiseptic gargles may be beneficial. —*Medical News*.

Surgery.

A MODIFICATION OF SENN'S METHOD OF ESTABLISHING LATERAL INTESTINAL ANASTOMOSIS.—DR. W. SACHS, assistant to Professor Kocher, of Berne, describes (*Centralblatt für Chirurgie*, October 4) a modification of Senn's method of forming lateral anastomosis between two separated portions of intestine. Senn's procedure of applying two bone plates is held to be not free from danger. The sutures with which the plates are armed, after they have been passed through the intestinal walls and tied together, are enclosed within punctured walls, through which capillary communication may be established between the interior of the intestine and the peritoneal cavity. A small abscess may be set up around one of the threads cut very short and enclosed on every side by the opposed serous surfaces of the two portions of the gut. Another danger, pointed out by Helferich, is gangrene of the intestinal wall, due to pressure of the bone plates. Sachs proposes the use of an appliance resembling in form a sleeve stud perforated in the middle. This is made up of two bone plates fixed together, yet separated to a small extent from each other as far as the uniting portion immediately around the central perforation. A longitudinal incision having been made in each of the opposed portions of intestine, each disc is inserted into the intestinal canal on either side, and the intestinal anastomosis is thus readily and speedily established. Sutures are then applied through the serous membrane on each side wherever there is a tendency to protrusion of the mucosa. The

following advantages are claimed for this method, which, however, has as yet been tested only in experiments on rabbits: 1. The interior of the intestine is not exposed for so long a time as it is in Senn's operation. 2. The margins of the intestinal wound rest in the deep annular groove between the joined discs, and are thus protected against infection and the results of pressure. 3. There is no risk of the cut edges adhering together. 4. It is unnecessary to pass any suture through the whole thickness of the intestinal wall.—*Brit. Med. Jour.*

Obstetrics.

ALBUMINURIA IN PREGNANCY.—EHRHARDT AND FANRE (*Nouvelles Archives d'Obstét. et de Gynéc.*, September, 1890) discuss this subject in relation to a mild attack of puerperal diphtheria in the Paris Maternité. They sum up past theories which have influenced treatment. Rayer traced the albuminuria to hydræmia, which exists during pregnancy. He had noted that injections of water into the veins of an animal caused albuminuria, but this fact does not prove his theory. Claude Bernard traced albuminuria to a state of supralbuminosis in pregnancy. Injections of white of an egg into the circulation caused albumen to appear in the urine. Gothwald and Monas held that the phenomenon was caused by increased blood pressure, the gravid uterus compressing the aorta below the renal arteries. Others believed that the uterus, by pressure on the ureters, caused renal disease. Lastly some pathologists traced the albuminuria to nerve influences carried on by communications between the uterine and renal plexuses. None of these theories, says Drs. Ehrhardt and Favre, explain why pregnant women suffer from albuminuria only in exceptional cases. They trace the complication to local disease. They examined 300 placentæ. Of these 20 were from cases of albuminuria. In 19 of these placentæ white infarcts were detected, and all the patients except two were subject to severe leucorrhœa when not gravid, and often to colicky pains during menstruation, symptomatic of endometritis. Colonies of bacteria were found in the infarcts, and when some germs, taken from infarcts in the placentæ of patients who had suffered from eclampsia as well as albuminuria, were injected into the veins of rabbits and guinea pigs, parenchymatous nephritis was set up. Thus the morbid changes in the decidua which cause placental infarcts are induced by the same agency that induces the nephritis of pregnancy. This agency is the presence of germs in the placenta, which germs produce in non-pregnant patients leucorrhœa and other symptoms of chronic endometritis. The focus of infection being the uterine mucous membrane, that structure requires attention and treatment. When

it is unhealthy the patient may repeated bear foetuses which die before birth through disease of the placenta—that same disease which, in the opinion of Drs. Ehrhardt and Favre, cause the nephritis of pregnancy with consequent albuminuria. They intend shortly to describe the precise nature of the disease in the kidneys in these cases. The moral they would draw is—Never neglect uterine discharges.—*Brit. Med. Jour.*

Pædiatrics.

CROUPOUS PNEUMONIA.—JOHN PLAYFAIR, M.D., in *Edinburgh Med. Jour.*,—The treatment should be mainly expectant, and therefore little need be said of it. Continuous hot moist applications to the chest were not employed. Such applications I believe do harm. They impede the movements of the chest by their weight, tend to increase fever, and generally are anything but comfortable.

All the counter-irritation required is secured by the application, to the back of the chest, of a few hot linseed meal poultices sprinkled over with a little mustard. Each poultice should be kept on for about twenty minutes, and in the intervals the chest enveloped in a light layer of cotton wool. Internally, if the cough is troublesome, an occasional dose, according to age, of a mixture of equal parts of syrup of tolu and syrup of chloral should be given. If the patient seems to be getting exhausted, and the pulse becoming rapid and feeble, the chloral and tolu mixture should be stopped, and a mixture of carbonate of ammonia, tincture of digitalis, and infusion of senega given instead. This mixture is often required about the time of the crisis or immediately after, as already mentioned. Alcohol was also usually given at this time.

As regards antipyretics, I find tepid sponging is by far the safest and most effective means of bringing down temperature in children. It is easily carried out, and a skilful nurse can sponge the patient as often as necessary without in the least disturbing or exposing him. My rule is to sponge whenever the temperature reaches $103\frac{1}{2}^{\circ}$, and to do so every two hours till the fever is reduced two degrees. Antipyretics, such as antipyrin and antifebrin, are given in some cases also, and usually with good effect. Occasionally, however, the effect is greater than expected, and the consequent exhaustion more pronounced than desirable. For that reason, chiefly, I prefer the sponging, unless in a case of hyperpyrexia, as in cases where the temperature runs up to 106° and 107° , when antipyrin and antifebrin should be used and the wet pack also resorted to. I prefer antipyrin to antifebrin as being decidedly less depressing.

During convalescence, iron, maltine, and cod-liver oil are the chief medicinal agents relied upon.—*Archives of Gynecology.*

SATURDAY, FEBRUARY 7, 1891.

THE TREATMENT OF THE INFECTIOUS DISEASES.

Up to the present time, two methods have been proposed and successfully practiced in the treatment of the so-called infectious diseases. Three of these diseases, small pox, anthrax and hydrophobia, we believe, are successfully stayed in their destructive course by the immunity which follows an infection with the attenuated virus of the respective disease. For small-pox, we have two methods equally successful, "inoculation" and "vaccination." They are practically illustrations of attenuation of infection produced in two different ways.

Only one of the chronic infectious diseases, syphilis, has so far been successfully treated, and by a method radically and entirely different. The remedial effect of mercury and iodine upon this disease is as anomalous as it is unparalleled. It is not to be compared with the treatment of malaria by quinine. To state the matter simply: three acute infectious diseases are successfully treated by attenuated infection, and one chronic infectious disease is treated successfully by the use of mineral alteratives. No other mycotic infectious disease pretends to any preventive or curative treatment.

From so limited a datum, it would perhaps be unwise to draw very positive deductions, but it may be worth while to speculate on the presumptions of the cure for tuberculosis lately proposed. This disease is to be classed with syphilis among the chronic infectious diseases. It is essentially an obligate parasite of the warm blooded animals, as syphilis is a close parasite of man. It would

seem from analogy that some alterative medication might be instituted in this disease as successful as the application of mercury in syphilis. Therefore we are not bound by our previous knowledge to look with suspicion upon the hypodermic medication proposed by SHURLEY and GIBBS. They recommend a well tried and a surer way of administering such remedies as are too unstable to be absorbed unchanged by the stomach. Their claims are not sensational and their methods are unobscured by secrecy or reserve.

The injection of the products of parasitic mycotic growth advocated by ROBERT KOCH is a line of treatment which has no parallel in our experience. It can not be compared with inoculation to which it is most closely related, and it is wholly different in principle and action from the treatment so successfully practiced in our only other chronic infectious disease. It rests then wholly on the authority of the author who has not yet had an opportunity to demonstrate its action and ultimate value. If it succeeds, we shall have added to our therapy another method, before the promises which inoculation offers have been demanded by investigation and fulfilled by experience.

There still remains perhaps the saddest category of ills to which civilization has exposed man in the facultative parasitic diseases,—the "filth diseases." Of these only one class has yet been conquered, the infective wound diseases. Suppuration, erysipelas, malignant edema and other hospital diseases have become so rare that they are objects of curiosity in our large clinics, but typhoid and diphtheria remain with us, the cause of almost five per centum of all deaths in our larger American cities.

Is it unreasonable in us to expect that every acute infectious disease will ultimately be overcome and its ravages stayed by the immunity which follows inoculation with an attenuated virus, and that each of the chronic infections will be disarmed by some such alterative as we have found so efficient in syphilis, and that the filth diseases will disappear when an educated intelligence guides our individual and collective life?

In some distant country, there are those in high position who seriously doubt the efficacy of vaccination, and it is rumored that antivaccination societies exist there. Even in our own

country some good people doubt the propriety of using mercury for syphilis, and PASTEUR'S treatment for hydrophobia. Is it wonderful, then, that the most stinging sarcasm is exhibited against SHURLY and GIBBS to whom attention has been drawn by the more startling and almost coincident announcement of ROBERT KOCH? Prejudice should not have an audience and there should be nothing *ex cathedra* in medicine.

SIR ANDREW CLARK'S PATIENT: A CLINICAL SKETCH.

SIR ANDREW CLARK has an apt and deft way of lighting up his subjects by means of clinical illustration. Not long since he was led to make public some of his views regarding the non-tubercular and non-cardiac hæmoptysis of elderly persons, when he brought forward the following illustrative cases:

Some seven years ago, Dr. Wilson Fox, Sir William Jenner and I were summoned to consult together about a lady suffering from an incoercible hæmoptysis. She was a Jewish lady, over 60 years of age, very stout, very rheumatic and always ailing. She had nodular finger-joints, frequently recurring bronchial asthma, and occasional outbreaks of either eczema or urticaria. Ten days before our visit, when suffering from ordinary catarrh without any accompanying fever, the patient began to suddenly cough up blood and had continued to do so, in small quantities, at intervals of three or four hours since that time. The patient had a somewhat large heart, but there was no murmur, and there was no evidence of systemic arterial disease. Within the two days previous to our consultation the pulse had become more frequent and quick and the temperature had risen to 100° nearly. In the lungs there were signs of a generalized bronchial catarrh, of emphysema and of basic congestion. The patient complained of frequent cough, of great oppression of the chest and of a growing difficulty of expectoration. She had, furthermore, a loaded tongue, thirst, loss of appetite, a swollen liver, and all the signs of a gastro-enteric catarrh. She had been carefully treated by absolute rest, fluid food, ice to the chest, and in succession by lead, gallic acid, and the hypodermic injection of ergotin. After full discussion it was determined that another method of treatment should be tried. The patient was ordered to have a light and rather dry diet, to be sparing in the use of liquids, to discontinue the ice, to have a calomel pill at night, followed by a saline cathartic on the following morning, and to take an alkaline mixture with ammonia between meals twice a day. Within thirty-six hours the hæmoptysis had ceased and the patient made a speedy and complete recovery. About a year and a half ago the lady again consulted me on account of a subacute rheumatic arthritis. She told me that since she saw me first she had had one attack of

bleeding and it had yielded promptly to calomel and salines. The contention of Dr. Clark in regard to hæmorrhages of this type is that they are liable to occur and recur in elderly persons of a rheumatic diathesis, but who are free from organic disease of the heart and lungs, that they arise out of minute structural alterations in the terminal blood vessels of the lungs, which alterations are akin to the vascular changes found in the osteo-arthritis articulations, and are themselves of an arthritic nature, and that while this hæmoptysis may at times lead to a fatal result, it usually subsides without super-vention of any coarse anatomical lesion of either heart or lungs. The use of astringents in large doses appears to be productive of harm chiefly for the reason that it tends to create great thirst, for the allaying of which the patient resorts to an unrestricted indulgence in liquids which seems to perpetuate the trouble.

UTERINE MEDICATION AND UTERINE SURGERY.

At the meeting of the Philadelphia Obstetrical Society, December, 1890, DR. CHARLES P. NOBLE presented a paper upon "Minor Uterine Surgery," which seems to us timely, since it is neither on the one hand excessively conservative, nor on the other unduly aggressive, in its recommendation of surgical procedures.

It might be inferred, he says, that gynecology had been so fully occupied with the surgery of its appendages that the uterus itself had been neglected, perhaps from the fact that the methods of the treatment of that organ had been placed upon an enduring basis and needed no restatement. But since, in a recent paper, the accepted methods of uterine treatment are called in serious question, he believes himself warranted in a review of generally accepted teachings.

He insists that a sharp distinction should be made between diseases of the uterus and diseases of its appendages, and this distinction is rendered the more emphatic, since it will control rational conclusions as to operative procedures.

Barring neoplasms, he claims that uncomplicated diseases of the uterus seldom or never threaten life. Not so, when its appendages are involved. When these are diseased, to tamper with the uterus is often but seriously to chance more aggravated conditions of diseased appendages.

Referring to the use of the uterine sound, he regards the field for its use as a limited one, and believes that more harm than good comes from it, as used to-day. It is serviceable in the diagnosis of obscure morbid conditions of the pelvis, but he holds that the size, shape and position of the

uterus can be far more accurately determined by bimannal examination than by its use. As to intra-uterine medication, he deprecates the freedom with which it is practiced, and considers the cases rare in which benefit is derived from the application of remedies within the internal os uteri.

The dilatation of the cervix is advised in the cure of obstructive menstruation for sterility due to flexion of the uterus, for the removal of polypi, small fibroid tumors, and the retained products of pregnancy. Rapid dilatation is advised and the steel dilators of Dr. Goodell's pattern are preferred.

The curette is considered indispensable in the treatment of uterine fungosities for the removal of endometrium, in certain cases of obstruction and congestive dysmenorrhœa, and for the removal of necrotic tissue after incomplete miscarriages.

But the utmost care is enjoined as to the manner of its use—the cervix having been previously dilated, and the finger preceding and guiding in application. The patient during its employment should be thoroughly anesthetized and antiseptics is to be carefully maintained.

The subject of the medical and surgical treatment of lacerations of the cervix, we think, is exceptionally well considered, but space does not permit its reproduction. The discussions to which the paper gave rise were able and instructive and we hope they will pave the way to a more extended consideration of the subject in the special Section at the next meeting of the Association.

FRAGILITAS OSSIUM.

DR. RODDICK, of Montreal, has had an unusual case of this affection, which is noted in the *Montreal Medical Journal*, November. The patient, a boy, aged 13 years, had received a fracture of the right thigh when 1 year old, and again when 3 years old the surgeon had been called to set a second breakage in the same bone. Since that time the boy had not had less than twenty-five other fractures of the bones of the lower extremities, the left femur being at present ununited. DR. RODDICK purposes at a near date to amputate both limbs, as they are in their present condition quite useless and extremely atrophied. There has, as a rule, been an entire ab-

sence of pain in the setting of the fractures. So far as could be learned, there had been no history of goitre in any member of the family; the brothers and sisters of the patient were in good health. Union of the broken bones at first took place with an abundant new growth of osseous material, but the more recent fractures have refused to unite so readily. The fractures were produced by a very slight amount of violence and were attended with little or no pain. The bones of the trunk and upper extremities have shown no defective tendency. DR. MILLS, commenting upon this case, adverted to an analogous, though less marked, defect often seen in certain of the larger breeds of dogs, such as the St. Bernards, mastiffs and great Danes, which were now bred of enormous proportions: the quantity of bone produced is relatively disproportionate to its quality, hence an imperfect osseous development in puppy-hood, and an occurrence of permanent deformities, especially in the hind limbs.

EDITORIAL NOTES.

A NEEDFUL CORRECTION.—We very much regret that our esteemed confrère of the *Cincinnati Lancet Clinic* should have been so unfortunate as to the sources of his information with reference to the circulation of THE JOURNAL in Chicago.

It should be premised that in no instance is THE JOURNAL furnished either as a perquisite or as a gratuity to any individual connected with either its editorial or publishing department.

We are at a loss to know how the *Lancet-Clinic* could have been so misinformed, as to state that the Chicago circulation of THE JOURNAL is one hundred and sixty-two copies per week, whereas a reference to the mailing list shows the exact number to be two hundred and sixty-seven.

The writer also argues a greater interest for THE JOURNAL in his city, from the fact that one physician in every six in Cincinnati takes THE JOURNAL. The exact number of copies taken in Cincinnati is ninety-four. This estimate would give to that city only five hundred and sixty-four physicians, a much less number than we had supposed.

It is neither our purpose to vaunt the praises of the medical profession in Chicago nor to discuss the question of the removal of the THE JOURNAL to Washington. But when the effort is made to

discredit THE JOURNAL and the place of its publication—that effort by so far as it is successful can only bring damage to our advertising interest—to an extent which we are confident the *Lancet-Clinic* does not intend. Competing interests are so sure to avail themselves of such statements that our duty to THE JOURNAL requires that we make the correction. We know of no instance in which THE JOURNAL has not the kind wishes of the medical men of Chicago, and without any boastful spirit we deem it our duty to state that of the income of THE JOURNAL derived from all sources, in the entire United States, *one-seventh of that amount comes from Chicago alone.*

PROVISION FOR NURSES.—The members of the medical profession are quick to recognize services rendered by competent and well trained nurses. Patients who appreciate their services are grateful for such care as they alone can render. It must not be forgotten that these nurses in the faithful performance of their duties are broken of rest, often overtaxed in the performance of their arduous duties, closely confined in the sick room, and are especially exposed to its contagions.

It can not be a matter of surprise that not infrequently they themselves become the victims and require medical care and skilful nursing. It would bring cheer to many of these if they knew that, whether they had means or not, a place of rest and treatment awaited them, in case of sickness.

The Philadelphia Polyclinic has taken a step in this direction, which we hope will stimulate to similar action in every American city. During the past year four free beds have been endowed and arrangements have been made with the Nurses' Beneficial Association whereby any member taken sick while practicing her calling is cared for free of cost.

It is a good thing to endow free beds in our hospitals; and it is a specially good thing to provide for those who imperil their lives in the service of the sick. Will the benevolent men and women of our country bear in mind the needs of our valuable nurses?

PROF. VAUGHAN'S ALLEGED DISCOVERY OF A TYPHOID "LYMPH."—Immediately before going to press with this issue a "special" from Ann Arbor, Mich., appeared in the public print heralding the discovery by Prof. Vaughan of the micro-

organisms of typhoid and cholera infantum, and representing that the medical world was upon the eve of another sensation—from inoculation results—not unlike that so recently occurring at Berlin. Upon telegraphic communication with Prof. Vaughan an unqualified denial has just been received by THE JOURNAL; yet the evil and annoying effects of the first report will scarcely be undone. That experiments are being carried on in the direction indicated, and under the careful eye of this investigator, is well known; but the time has not yet arrived for the advancement of the strong statements just put forth.

SPECIAL COMMITTEE.—The following gentlemen are named as the Committee on Organization and by-laws of the National Association of Medical Colleges: Dr. P. H. Millard, of St. Paul, Chairman, Dr. William Osler, of Philadelphia, and Dr. Samuel Logan, of New Orleans. The Committee will report at the forthcoming meeting to be held in Washington.

SECTION OF NEUROLOGY AND MEDICAL JURISPRUDENCE.—The Secretary of the Section on Neurology and Medical Jurisprudence, desires to call the attention of members to the fact that the scope of this Section has been enlarged, and neurological contributions, that formerly belonged to the Section on Practice of Medicine, may now be read in the new Section. The Secretary's address is Dr. Harold N. Moyer, 434 West Adams St., Chicago, Ill.

WORTHY RECOGNITIONS.—Three new chairs have been recently created in the Philadelphia Polyclinic and College of Graduates in Medicine, in the department of surgery, and Drs. John B. Deaver, S. D. Risley and Arthur W. Watson have been called to their occupancy.

DR. KOCH AS A COUNTRY DOCTOR.—The *New Review*, December, contains a sketch of Dr. Koch while he was a country practitioner in Posen. "To eke out a respectable living he pursued the career of a family physician. On many a Polish winter night, jolting in a Polish rural car along a Polish country road, the indefatigable man would drive about to look after a coughing child or an expiring boor, having previously torn himself away from his books to render what assistance he could and earn what little fee he might. A serious, unostentatious and dutiful man through-

out, he, in this and in every other part of his career, commanded the respect of his fellow-citizens, without, however, eliciting any very ardent feelings in his behalf. He never spoke much, though his actions might always be relied on. He never displayed a tendency nor indeed a wish to shine, though he certainly was a proficient in the rare art of doing good. Night and day, in sick-room and in hospital, he had little time to devote to the society of his equals, and in that half Sclavonic province was certainly more popular as a doctor than as a visitor or a host."

BACILLI TUBERCULOSIS IN THE SPUTUM.—That the discovery of bacilli tuberculosis in the sputum may now be said to unquestionably indicate the presence of the peculiar pathological condition we have so long helplessly considered, stands quite without fear of contradiction; yet it seems by no means certain that the absence of microorganism will at once lift the veil of apprehension. Dr. Ludwig Weiss, of New York, states (*New York Medical Journal*) that he has labored with no less than forty different specimens in the same case before "the long-sought for little red bacilli could be brought to view under the microscope," and his argument at once comes that in "the lack of tubercle bacilli is, therefore, not an evidence of the absence of tuberculosis."

This fact should only tend to lead still more to the reliance vouchsafed from the reaction produced by the "lymph" injection.

MEDICAL ITEMS.

THE HYPNOTIC LIMIT.—According to Charcot, not more than one in 100,000 is subject to the hypnotic influence.

ENGLISH CHARITY.—On hospitals alone the English people spent £598,220 in the last year. Taking into account home and foreign missions, religious and benevolent societies, along with provident dispensaries and convalescent institutions, it is computed that every man, woman and child in the United Kingdom contributes three shillings a year.

FACTORY MEDICAL SERVICE IN RUSSIA.—The Russian Government is about to issue an order according to which: 1. every factory or mill situated at 8 *vershs* (about 8½ kilometres) or more from a town shall have a hospital of its own, containing from ten to seventy beds, accord-

ing to the number of hands employed by the proprietor, as well as its own dispensary; 2. a special doctor and a medical assistant (*Feldscher*) must also be in attendance; 3. the district medical officer must exercise sanitary control of all factories and mills existing in his district.

MEDICAL DIRECTOR JOHN V. TAYLOR, who has been President of the Naval Examining Board for a long time, has just been retired from active service on account of age. If we are correctly advised, Medical Inspector Grove S. Beardsley will be promoted to the vacancy, and Surgeon Edward Kershner, on duty at the Marine Rendezvous, New York, to Medical Inspector, and Passed Assistant Surgeon Samuel H. Dickson, with the "Atlanta," will be promoted to Surgeon.

RESECTION OF THE LIVER.—On December 8, Professor Iginio Tansini, of Modena, performed total extirpation of a hydatid cyst of the liver, at the same time excising a portion of that organ. There was very free hæmorrhage from the large cut surface of the liver, which was controlled by catgut ligatures. The wound in the liver was closed by means of sixteen sutures, partly silk, partly catgut. The operation was followed by no rise of temperature, and the patient (a woman) was quite well in less than a fortnight.

PROFESSOR BARTHOLOW'S SUCCESSOR.—The Trustees of Jefferson Medical College have elected Dr. A. P. Brubaker as the successor to Prof. Bartholow in the Chair of Materia Medica and General Therapeutics.

THE RELATION OF ALBUMINURIA TO PUERPERAL ECLAMPSIA.—Dr. Wm. S. Gardner (Lecturer on Obstetrics in the College of Physicians and Surgeons, Baltimore) in a paper on this subject, arrives at the following conclusions, which are based upon a number of cases cited:

1. The presence of albumen in the urine of a pregnant woman is no sufficient cause upon which to base a prognosis of probable eclampsia.
2. The failure to find albumen in the urine of a pregnant woman is no evidence of the absence, or, at least, of the continuance of the absence, of the condition that gives rise to puerperal convulsions.
3. Albumen is so frequently found in considerable quantities in the urine of patients immediately after the appearance of puerperal convulsions, that we are justified in making the statement that the convulsions are the probable cause of the albuminuria.

TOPICS OF THE WEEK.

DR. KOCH AND THE GERMAN GOVERNMENT

A well-informed correspondent writes: During the last fortnight various rumors have been telegraphed from Berlin as to the arrangements made, or about to be made, between the German Government and Professor Koch with regard to the future production of his remedy for tuberculosis, and it must be admitted that these rumors have been of a somewhat disquieting character. It has been said that Dr. Koch and each of his assistants, had accepted a large immediate payment, and that they were to receive a royalty upon all sales in the future. Thus stated, the arrangement, it must be admitted, would partake far too much of the commercial transaction to be agreeable to the traditions of the medical profession, or the customs of men of science. It is, however, easy to give an unfavorable complexion to a transaction really of an honorable nature by inverting the steps by which the final results have been obtained and so misrepresenting their character. It may be well to recall the circumstances under which the lymph has been discovered, and the position of Dr. Koch in relation to the German Government. Dr. Koch has been for many years the director of the Hygienic Laboratory in Berlin. This laboratory is a Government institution, maintained by the Educational Department of the German Government, and Dr. Koch, as its director, has been an officer of that department. All the earlier experiments for the discovery of the now famous lymph were conducted in Dr. Koch's own laboratory in the Hygienic Institute, and there the observations upon guinea-pigs and other animals, which emboldened Dr. Koch to proceed to inoculate human beings, were made. The laboratory, however, presented no facilities for making these investigations upon human beings, and Dr. Koch holds no official position with regard to any of the Berlin hospitals. He therefore found himself in a practical dilemma, inasmuch as if he were to make his experiments in a public hospital it was feared that the premature and eager discussion of incomplete observations and immature results might easily tend to interfere materially with the investigations and to produce evil results. Dr. Koch consequently hired a private house at his own expense, and obtained the assistance of two gentlemen with whom he had private acquaintance—Dr. Libbertz, an old school-fellow, and Dr. Pfuhl, his own son-in-law. The lymph was prepared in considerable quantities in this private house by these two gentlemen under Dr. Koch's supervision, and the earliest injections in man were made in the private hospitals of Drs. Cornet and Levy. It soon became evident, however, that the interest, both among the general public and in the medical profession, was too keen to permit of the continuance of the investigation upon these lines; and Dr. Koch, acting on the advice, or perhaps it might be correct to say upon the instructions, of Herr von Gossler, the Minister of Education, published the now famous preliminary paper, and distributed the lymph to certain of the hospitals in Berlin. Meanwhile, the manufacture of the lymph was carried on in the pri-

vate house by Dr. Koch and his two personal private assistants. Recently this arrangement has ceased; the house in which the lymph is manufactured has been taken over by the Education Department of the German Government, and Drs. Pfuhl and Libbertz have become officers of that department. The Koch Institute, which the German Government are now erecting, will consist of two parts—a laboratory and a clinical department containing 150 beds. The clinical department will probably be under the direction of Professor Brieger. The observation and treatment of the patients received into it, it is hoped, will afford in the future opportunities for Dr. Koch to prosecute his studies with regard not only to tuberculous diseases, but to tetanus, diphtheria, and typhoid fever. In this way the inconvenience which has arisen from his having no clinical wards of his own will be avoided.

In the laboratory bacteriological investigations will be carried on, and at the earliest possible date the laboratory for the preparation of the anti tuberculous liquid will be transferred to this department of the Koch Institute. The director of this bacteriological department has not yet been appointed, but the whole institute will be under the general direction of Dr. Koch, who will remain an officer of the Education Department. It is probable that the German Government will offer to Dr. Koch some recognition of the great services he has rendered while acting as a German official, such as was voted to Jenner for his services in a cognate research, and more recently to Pasteur, in France. Large national awards have repeatedly been made to successful generals in Germany and in other countries, and it is felt that there is no reason why a man of science, who has worked for the relief of human suffering, should hesitate to accept a reward which the destroyers of men have never felt the least difficulty in receiving. As to the further rumor that Dr. Koch and his assistants may receive a payment as it were by results in the future, it may be hoped that this rumor is unfounded. Anything like the sale of a secret or the paying of royalties on a remedy would be contrary to the Hippocratic tradition.—*British Medical Journal*.

GROWING KNOWLEDGE.

The editor of the *Educational Times* has been insisting in a recent article upon the importance, as he puts it, of "growing knowledge" in the minds of children. The lesson is one which teachers as a body are, perhaps, slow to learn, but it has certainly obtained a considerable amount of recognition in recent times. But, notwithstanding, the parable of the *Educational Times* is always seasonable. It is pointed out that knowledge must be apprehended, appropriated and assimilated by the mind very much as the elements of vegetable tissue are apprehended, appropriated and assimilated by a plant. There is a sense in which every student may adopt the aphorism maliciously attributed to the "Master of Balliol College," that

"What I don't know isn't knowledge."

The binomial theory is useful information for anybody, and indispensable knowledge to the mathematician, but

to such as have but little mathematical faculty it is information, and nothing more. So with the Greek syntax or Latin composition. To the classic they are elements of knowledge, to the pedant mere shreds of information which never germinate in his mind, and are incapable of ever becoming fused into a coherent habit or scheme of thought. In the acquisition of such indigestible materials there is much pain and very little profit, and it cannot, therefore, be too often or too forcibly brought to the minds of teachers that their true function is not to fill a vacant mind, but to preside over the birth and development of nascent faculties. If the faculties are supplied with suitable pabulum they will spontaneously exercise themselves upon it. The wise teacher is he who happily discerns what faculties are dominant in his pupil, and what treatment is best adapted to stimulate and develop them. This view of a teacher's work receives, we believe, a much more general and effective recognition at the present than at any former period, and we are glad to find it from time to time put prominently forward in the accredited organs of the teaching profession.—*Lancet*.

TREATING CONSUMPTION BY MEANS OF INHALATIONS

In the December number of the *Harper Hospital Bulletin*, Dr. Shurly publishes, with illustrations, his method of treating consumption by means of inhalations. Chlorine gas, in the presence of the vapor containing chloride of sodium, forms an important element in the treatment, and he is sanguine his plan possesses great curative virtues. He reports a number of cases illustrating the variations in applying the method. It does not appear that he neglects the provision of a pure atmosphere, of suitable food, and all the other well-known agents by which this disease has been combated; so that the question respecting his specific treatment is to determine the benefit derived from the old measures, plus the faith awakened by the use of the new, and the new by itself. When he is able to show this then the profession will be in position to determine the exact value of the new features which he has contributed. We shall all hope that these are equal if not greater than Koch's claims for his "lymph." Too many remedies for the cure of consumption cannot be given the profession.—*American Lancet*.

IMPORTANCE OF A DEPARTMENT OF RAILWAY SURGERY.

The railway surgeon has long since served the probationary period once allotted him and is now a fixed fact. He has already proved himself a financial reality and has come to stay. When we consider that notwithstanding all the consolidations of various railroad lines into great systems, and thereby the abolition of many lesser lines, there are still, in round numbers, about 600 independent systems of railroads in this country employing almost 1,000,000 men daily, who are in constant danger to a greater or less extent, according to the position they hold, of receiving personal injuries, saying nothing of passengers and others subject to the same dangers, it is certainly very easy to see the necessity of maintaining regularly organized departments of surgery, not only for

the protection of the employees alone, but for the general protection of the nation from exorbitant and fraudulent claims.

Allowing an average of but ten surgeons to each independent system it would require an army of 6000 surgeons to perform the services required by the railroads of our country, which estimate we are certain is far below the reality.

We doubt whether the standing army of the United States to-day numbers over 200,000 men, or whether works an average of about one soldier to every forty railroad employees, and the soldier in time of peace is not exposed to even one-fourth of the physical danger that the average railroad employee is subjected to; and yet the federal government has long since settled the question of the necessity of maintaining a well organized and well paid corps of surgeons, not for the protection of the soldiers alone, but for the protection of the government against fraudulent claims for pensions; and notwithstanding all this, the government is to-day undoubtedly paying many questionable pension claims every quarter.

Of course there are railway companies even at this late day which do not employ regular surgeons, but that does not prove that it is economy not to do so, or that their success is due to such policy. Not long since we were told by the general manager of one of the largest railway systems in this country, a gentleman whose success as a railway executive is unquestioned, that he would just as soon think of parting with his freight department as to dispense with his department of surgery. He went on to say that he spoke from years of experience that had proven to him the facts on which he had based his opinion; and we will add in addition to what he has said, that no better system of surgery is conducted on any railroad in this country than on the road he represents.—*Railway Age*.

A NOBLE RECORD

It is said of Dr. Kerr, a medical missionary of the Presbyterian Board at Canton, that he has in the past thirty-six years treated over 520,000 patients and has prepared twenty seven medical and surgical books. He has trained 20 medical assistants, chiefly Chinese.

SANITATION AND BACTERIOLOGY IN AUSTRIA

The Chamber of Deputies in the Austrian Parliament considered on December 12 the report of a commission appointed to inquire into the proposals made by a Deputy, Dr. Roser, for the creation in Austria of an Imperial Sanitary Bureau, after the model of the institute established at Berlin for the whole of Germany. The report recommended the adoption of a series of resolutions demanding the foundation of chairs of hygiene and bacteriology in the faculties of medicine, the introduction of hygiene into the medical curriculum as an obligatory subject, the improvement of the public sanitary service by an increase of the number of doctors nominated by the State, and a general reform of the pharmaceutical department. In the course of the debate attention was drawn to the advantages which Dr. Koch had enjoyed in the Imperial Sanitary Bureau at Berlin, and satisfaction was expressed at the recent decree of the Austrian Minister of Instruction dealing with the question of hygiene in schools.—*Brit. Med. Jour.*

SOCIETY PROCEEDINGS.

Chicago Medico-Legal Society.

*Regular Meeting, December 6, 1890.*EDMUND J. DOERING, M.D., PRESIDENT, IN
THE CHAIR.DR. HENRY M. LYMAN read a paper on
MONOMANIA.

(See page 190.)

DR. D. R. BROWER: Dr. Lyman has given the most salient feature of this most interesting form of insanity, and so scientifically that there is really very little to be added. There is one point for which I wish especially to commend the doctor, and that is his objection to the term "monomania," the designation by which these cases are known by most of the American and English alienists. As he has stated to you, there is nothing about these unfortunate people suggestive of mania. As a rule, there is no mental disturbance manifest in their daily talk—they are cool, calm and collected, seemingly, as the majority of persons in this audience; and the monomania of the designation is scarcely clinically true, because it is an exceedingly uncommon thing for any of these insane people to have their insane disturbances manifested only in a single direction. I commend Dr. Lyman especially for his preference for the word "paranoia." Paranoia, going back to its derivation, simply means a disturbed mind, and does not express any especial feature in the clinical history of these cases, but then it has the advantage of not teaching error. So far as it teaches anything it teaches the truth; they are persons of disturbed minds. There is about these cases of monomania so much plausibility, so much reasoning capacity, so much ingenuity in pressing home their vagaries, that they will pass, under almost any ordinary circumstances, as persons of perfectly sound mind. The great majority of them are not in the insane hospitals. They are to be met with by observing people very frequently; they are to be seen in our own profession. My attention was called the other day to the case of quite an eminent medical gentleman of this city who is undoubtedly a paranoiac, and yet he is a successful practitioner of medicine, not only in regard to the results of treatment but in the financial success that has attended his efforts. Quite recently he has been doing things that, to say the least, are very remarkable. He happened to meet casually a lady of this city of high social standing and undoubted virtue, and became enamored of her at once, without any acquaintance with her. He began sending her presents, he sent her several valuable diamonds, bouquet after bouquet, tickets to the theatre, and so on. She did not know from whom these things came, they were left at the door by a messenger, and that

was all that was known about them. The door bell would ring, the servant would receive them and the messenger depart. This man never had any conversation with her, but he became possessed with the idea that she was in love with him, as he thought he was with her. The thing became so annoying to her that finally the messenger was detained until a policeman was sent for, and in that way the identity of our doctor was determined.

I saw only a day or two ago a young lady of this city, a paranoiac, who is a most admirable stenographer; she is engaged to-day in the office of one of our prominent lawyers, and she must do her work in that office well or this legal gentleman would not employ her. She has been in his service for a number of years, and I do not suppose that he suspects her mental vagaries. She is one of those paranoiacs who are continually afraid of being befouled; she never touches anybody's person if she can help it, never shakes hands with any one, and if she should be so unfortunate as to be compelled to do so her hands must be immediately washed. She carries with her always what she regards as a powerful antiseptic, and after she washes her hands she cleanses them with this antiseptic. Some few years ago it seemed as if it would be necessary to deprive her of her liberty. She has now and then persecutory delusions about her family—she won't live with her parents, she sometimes lives with a sister, but frequently changes her place of residence on account of the persecutory delusions that spring up. It is a surprise to me how she has so long and faithfully pursued her occupation without her vagaries being suspected. As Dr. Lyman has told us, very many of these paranoiacs, or monomaniacs, while they are possessed of these delusions, yet outside of that they have a great deal of mental power, and some of them have done a great deal, in various ages, towards modeling society and forming religious societies. There are some that I scarcely dare mention in this community because I would be afraid of the storm that might be raised about my ears, but we mention Mahomet; you must all regard him as one of these paranoiacs. I think Peter the Hermit belongs there also, and Louis Riel, of Canada. And some of you must admit that Charles J. Guiteau is of the same class. The case of Guiteau was one of the most interesting that has been tried recently. In that trial the great leaders of psychological medicine were arrayed against each other; my distinguished and eminent friends Dr. Gray on one side and Dr. Spitska on the other; two great giants in psychological medicine arrayed against each other. Many facts in the history of Guiteau were ascertained after the trial that more fully brought out his paranoiac characteristics than anything that appeared at the trial, and I presume some of the distinguished psychological gentlemen who

were on the side of the prosecution might have thought differently had they been aware of these facts.

This brings up another very interesting question in reference to these paranoiacs, and that is as to their responsibility. That is a branch of the subject upon which Dr. Lyman touched very lightly, but is very important. While I am willing to class under this designation of paranoia a very great many persons who are outside of the insane asylums, yet I believe that the great majority of paranoiacs have at least a certain degree of legal responsibility, and had I been on that Guiteau jury I don't know that I would have brought in a verdict of hanging, exactly, but I certainly would have insisted upon imprisonment for life. I think these paranoiacs should be held to a certain degree responsible for crime. They have a certain measure of control of themselves—more than they are very often willing to exercise. The degree of responsibility should be determined in each case.

The paranoiacs are more or less dangerous people. Some one has said that if they lived long enough they would all of them be homicidal, and certainly there is more or less tendency in all to acts of violence, and they require restraint of some kind; I do not think they are safe people to be at large in anything like the proportion in which I believe they are. Let the occasion arouse their imperative conceptions, and their impulses, growing out of their delusions, may lead to acts of violence, and the danger of this is greater with their advancing years. Then there is another point about these paranoiacs that Dr. Lyman dwelt upon very lightly, but which is very important; that is the fact that most of these paranoiacs have other defects than the mental ones. The great majority of them come into the world with such defective construction that we can easily recognize them. There are defects in their general configuration, defects in the shape of the head, in the facial lines, in the arms, or in the legs. These departures from normal structure are often important aids to diagnosis.

I am very glad to have been present and heard Dr. Lyman's admirable exposition of this important subject.

DR. ARCHIBALD CHURCH: In view of the fact that the subject has been very thoroughly presented by my masters, the gentlemen who have preceded, it would not be becoming in me to detain you long with an attempt at further exposition of this matter. It is, however, one of great interest and of great importance. The difficulties arising from it are illustrated in Dr. Brower's remarks: He spoke of the legal responsibility in these cases and said that in the majority of instances a certain degree of responsibility must be attributed to them before the law. He also told us that in the majority of instances a

homicidal tendency would sooner or later be developed—a tendency for which they are not responsible. I am inclined to believe that in this form of disease there is a large degree of irresponsibility from the first, and this leads me to emphasize Dr. Brower's recommendation that more of these paranoiacs should be under control.

It is not necessary for me to go into the terminology of the affection except to point out that in some instances it has run wild. By some German authors every variation in the disease has received a special designation; for instance, an individual who had the peculiarity of stealing women's shoes was classified under the term "trauenschuhstehlmonomanie."

These paranoiacs are the people who are known in their communities as the "peculiar people," they are the men who ride their hobbies rough shod over everybody; they are called "cracked," and somebody has said that through these cracks sometimes light has been shed on the world, and that is true. Peter the Hermit, John Bunyan, Swedenborg were all paranoiacs. It is in these cases that genius is akin to madness.

In the case Dr. Lyman mentioned, the young man who considered himself the son of the actor Booth, and who not being recognized by him, after following and persecuting him with his attentions for a number of years, from one of the galleries of a theatre here fired his pistol at the actor on the stage, clung to his delusions until death. He believed himself a great actor, and subsequently sought vengeance against those whom he considered his oppressors. The man Joel Henry Wells, who presented in his family history well marked evidences of insane heredity, also to the day of his death clung to his delusions of grandeur, which fortunately in his case never took on the persecutory type. He believed himself the descendant of a noble French family and up to the time of his death signed himself Henri de Travis. After his liberation from the Elgin asylum, done by legal process under habeas corpus proceedings, and when he was pronounced sane and capable of caring for his property, by the judge, he entered into business in Chicago and conducted it satisfactorily, maintaining himself and family comfortably, but always signing himself Henri de Travis, and always insisting that he had been abused and persecuted. Scarcely a month passed that the hospital did not receive some communication from him threatening prosecution and suits for damage, and probably there is not a prominent lawyer in this city but has been approached by him with requests to take up these suits. At his death he bequeathed an enormous property which was as imaginary as his name. The peculiarity in this malady has been tersely expressed by Seglas as an hypertrophy of the ego. With these people it is always the great I am. This peculiarity distinguishes

them when they become depressed, this enlargement of the ego still persists.

The melancholic individual believes, on the other hand, that he has committed some crime or done some misdeed, that the blame is his own, but the paranoiac fancies that he has been sinned against and that because of his importance a conspiracy has been formed to keep him down; they look at the situation from diametrically opposite standpoints. Clouston tells of an old man of benevolent character and generous impulses, with a very liberal education, to whom was entrusted in his asylum the keeping of the books and a large share of the records. You might know this man for months and in his ordinary conversation he would never manifest any peculiarity, but he believed that two and two made four and a quarter. In deference to the prejudices of the asylum management he kept their books by the old method, but for himself he established a new system of arithmetic and mathematics; he constructed enormous tables of logarithms, and carried his theory through the higher branches of mathematics and left immense manuscript volumes to the University of Oxford, that his discoveries might not be lost to the world. It is these individuals who make so much trouble in the courts; it is, as you can all see, a matter of great difficulty to determine, sometimes, not only their insane state, but beyond that to determine how much they may be trusted with their liberty provided they are considered of unsound mind. A case which probably has many times come to your attention is the young man who pursued Mary Anderson for many years, being possessed with a platonic love for her and believing that love was returned. He was finally apprehended in New York and committed to the asylum; he clung tenaciously to this idea but in every other respect he seemed to be perfectly sane, yet this idea dominated his conduct and mental methods completely. Eventually he was liberated from the institution, contrary to the wishes of the management, and only a few weeks ago he returned to the asylum, full of the idea that he had been unjustly persecuted and deprived of his liberty, and with a revolver fatally shot one of the assistant physicians. His expressed intention was to shoot the whole staff.

I might point out to you that the great crimes done by insane men are done by those who are trusted. An insane man is dangerous, I believe, in proportion as he is trusted. If you know he is dangerous you will guard against him, but if you believe him trustworthy he has the opportunity of perpetrating terrible deeds. I am of the opinion that we should take greater pains and make more strenuous efforts to put in safe keeping these paranoiacs who now are going about the streets.

There is another point I wish to call to your attention; these individuals, in the vast majority

of cases, are afflicted with hallucinations of the senses, and very often of the sense of hearing. They hear the voices of people on the street calling after them with abusive epithets or in libelous terms; they hear commands from on high, as did John Bunyan; they may hear orders from the Almighty to kill. Whenever you find systematized, persisting delusions with hallucinations of hearing you will be safe in giving an unfavorable prognosis, because nine times out of ten they pertain to paranoiacs the majority of whom die in the insane hospitals.

DR. HENRY M. LYMAN: I hardly think I can add anything to what has been said, the ground has been very thoroughly covered. If there were time it would be interesting to introduce cases, but the details of the subject have been well presented to the Society by my associates. One point suggested itself to my mind with regard to Joel Henry Wells which it seems to me would throw light upon some of the conflicting opinions in reference to the relation of paranoia to other insanity, it being the opinion of some that all cases of systematized delusion should be called paranoia whether they be primary or secondary to other forms of insanity; but others claim that paranoia is always congenital and that it is hereditary. There was this fact in the history of Wells: he was committed to the asylum in a state of very great exaltation, acute mania was his condition practically at the time he was sent to the asylum, and his delusions assumed their greatest importance after that period of excitement. But this thing was brought out on the trial of the patient—the explosion of mania, which, if it had been an initial symptom and if there had been no history of any hereditary defect in the family, would have been looked upon as the starting point for the evolution of secondary paranoia; was shown to be only an incident in the course of disease, as the man had years before manifested symptoms of an unsound mind, having had delusions in regard to the location of property. His brother-in-law said that the first thing he noticed wrong was when he was going to build a house, that he insisted upon putting the house on the next lot to his own, he would have it that the house should be built upon another lot. At that time his friends looked upon that circumstance as evidence of unsoundness of mind. I have no doubt it was evidence of the congenital defect originating in antenatal influences, which at that time first showed themselves, for it is usual after the individual has grown up and reached man's estate for these to become most conspicuous.

Then the fact of there being marked symptoms of insanity without bodily disease is also worthy of note, for I think careful observation will in the vast majority of these cases show a very grave defect in the development of the body, so much so that when I see a person with certain marked

vagaries of form, feature, and cranial development I am almost instinctively led to suspect the existence of mental obliquity, at least. These cases are of the paranoiac type, and the disease seems to bear a relation to other insanity very much like that borne by congenital idiocy; and it should be classified with idiocy, since the obliquity of character and the development of peculiarities is dependent not so much upon the actual existence of disease of the brain as upon the workings of a badly formed and ill constituted brain. The matter of hallucinations is really very important, for it is sometimes the only evidence of the existence of this defect. A gentleman walked into my office the other day, who to all appearances was a man of excellent health and fairly well developed body, but it came out upon inquiry that he had been subject for years to paroxysms of suspicion. He would walk upon the street, and on reaching home would insist that somebody had insulted him, that somebody had looked at him in such a way as to show that they meant mischief; he had heard people whispering about him as he passed them, which led him to believe that they had designs against him. On one occasion a friend came to his room on business, and without any provocation this man leaped from his chair and dealt his friend a blow in the face, and a few days afterwards meeting him on the street he apologized for the act. I am convinced from the family history and characteristics of other members of the family that this is a case of indubitable paranoia—the incipient stage of paranoia, which may result suddenly some day in a violent explosion. These hallucinations of hearing that Dr. Church has spoken of are also very significant. I know a case in this city today of a professional man who presents in his general appearance all the characteristics of perfect health; he is a large, well formed, muscular looking person, and yet that man is and has been for a long time under the delusion that somebody is speaking to him. I have a number of letters from him telling how people are speaking and telephoning to him, and he has at last discovered that it is a conspiracy on the part of the Jesuits to convert him to Roman Catholicism, and these are the means which they take. In every other respect he appears like a man of good health, he is intelligent, talks freely about his case, but will not admit that he is insane. So it is with many of these cases. Dr. Brower has well said that they exist in all grades of severity from the dangerous homicide down to the person who simply labors under the delusion that there is a snake inside of him, or that there is some constant conspiracy working against his welfare. They are the cranks, the cracked persons, the eccentrics of society. Many of them by their very eccentricities, the one-sided nature of their characters, have accomplished a great deal of good in the world as

well as a great deal of harm. I think that in this State we are laboring under the injustice of a law regarding the commitment of the insane that was procured by one of these persecutory paranoiacs.

Allegheny County Medical Society.

Special Meeting, November 18, 1890.

W. S. FOSTER, M.D., PRESIDENT, IN THE CHAIR.

Concluded from page 175.

DR. MURDOCH reported the following case:

DISLOCATION OF THE HIP REDUCED BY MANUAL EXTENSION.

S. B., a powerful young man, was brought to the Western Pennsylvania Hospital last Friday (Nov. 14), presenting the usual symptoms of an upward and backward dislocation of the head of the femur. He stated that two hours previous to his admission, while engaged in pushing a car loaded with coke along the track, bending forward and exerting all his force, another loaded car unexpectedly came up behind and struck him with great force upon the buttock, forcing him against the car which he had been pushing. When he had been disengaged from the position in which he had been caught, he found that he was disabled in the hip. A number of physicians had been immediately called, and an attempt made to reduce the dislocation. This attempt having failed, he was at once sent to the hospital.

Upon examining the patient, it was evident that the head of the right femur was dislocated upon the dorsum of the ilium. The patient was a very powerfully built young man, with unusual development of the muscles, especially those of the gluteal region. For this reason, before any attempt at reduction was made, he was most profoundly anesthetized. An effort was then made at reduction by the methods recommended by Reed, of Rochester, and Bigelow, of Boston. The leg was flexed upon the thigh, and the thigh upon the pelvis in an adducted position. It was then strongly abducted, rotated and extended. This manipulation was repeated several times, with a complete failure each time. Other manipulations were tried, with no better success, until the operators were entirely exhausted.

I then resolved to make use of extension, which had often before succeeded in my hands. A young medical student who was present was asked to remove his boot, and placing the foot on the perineum against the ramus of the ischium as a counter extending force, extension was made with the hands grasping the thigh and leg, the direction of the extension being across the middle of the sound thigh. In this position the thigh of the dislocated limb is flexed almost to a right angle with the pelvis. The surgeon is also called to

assist in the extension by standing behind the assistant who had his foot on the perineum. The surgeon can also, while in this position, change the direction of the force and rotate the limit as may be necessary. In this manner, at the very first effort, and without much force being used, the head of the bone slipped, with a sensation which could be felt, into acetabulum. Upon inspection and movement, the deformity had entirely disappeared.

While it has been my fortune to see a good many dislocations of the hip reduced by manipulation alone, still this is the seventh case of which I have knowledge when it has failed, and when extension applied in this simple manner has been successful.

A few years ago, I reported to the Medical Society of the State of Pennsylvania a history of six cases of this kind. This report may be found in the Transactions of our State Society for 1886. From the experience which I have had in these, and other cases, I am persuaded that this simple method of extension and counter-extension should always be resorted to before making the effort by manipulation.

The method by manipulation is not so harmless as some of its advocates assert. The shaft of the femur which is made use of when manipulation is resorted to, is the long arm of the lever, the Y ligament is the fulcrum, and the neck of the femur, with the force which can be applied to it, is liable to give way. Fracture of the neck of the femur has, in this manner, been produced by some of our best surgeons. Such men as Jas. R. Wood, Post, and Markoe, of New York, and many others, have had this accident happen while attempting to reduce dislocations of the hip by manipulation. But even if no fracture is produced, the sweeping round the acetabulum of the head of the femur, as occurs during this manipulation, lacerates and bruises the capsular ligament and other structures in an unnecessary degree.

The violence produced by extension in the manner which I have indicated, cannot produce such injury; and is, as I believe, more likely to succeed.

To Henry J. Bigelow, the distinguished Professor of Surgery in the Medical School of Harvard University, we are indebted for teaching us how important a part the anterior capsule of the hip joint (viz.: the Y ligament) plays in luxation. He has taught the profession that to reduce the dislocation it is first necessary to relax this ligament. This is accomplished by the method I advise, because the thigh is first flexed upon the pelvis before any extension is made. Moreover, we now know, that in nearly all dislocations of the hip, that it is the lower and inferior portion of the capsule which gives way. It is here that the acetabulum is most shallow and the ligament has least strength.

It is the opinion of our best modern surgeons that nearly all dislocations of the hip are primarily downward, and that when the head of the femur is found in any other position, whether upon the dorsum ilii, into the sciatic notch, or upon the pubes, that this position is secondary to the downward.

If this be so, and there is little doubt of its truth, it surely seems likely that the pulling the head of the bone downward to the place where the rent in the capsular ligament has occurred, is the best direction in which to apply the force.

In other words, the dislocated head of the femur must, in order to find its place in the acetabulum, retrace the steps which it took after leaving it.

I would, therefore, advise that in the reduction of a dislocation of the hip, no matter what the position may be, after thoroughly anesthetizing the patient, the attempt at reduction should be made in the manner indicated.

It is probable that much of the popularity which the method by manipulation has received, is owing to the fact that anesthetics came into general use by the profession about the same time that Reed, of Rochester, described his method of reducing dislocations by rotation and circumduction.

DR. BUCHANAN: I wish to say that I heartily agree with Dr. Murdoch in the position he has taken relative to the choice of methods of reduction, for the shoulder as well as the hip. I think the effort by extension should be tried first, for the reason that, as Dr. Murdoch well expresses it, by extension and without the use of pulleys, simply manual, no harm can be done; whereas, any man who has ever held a patient's thigh and put the head of the bone into its socket by the method of manipulation, could not but have felt grateful, when the head of the bone passed in its place, that he had not broken the femur. If he fails by extension, he feels that he has done no harm, but if he fails in his trial by manipulation, he feels that he may have done much harm. I think that the resistance of muscular tissues and fibrous tissues, when the patient is thoroughly under the influence of an anæsthetic, is very much over-rated. Within a couple of weeks, I have put in two shoulder-joints by the method of extension without anæsthesia, and with no trouble whatever, almost lifting the head of the bone into place. One was an exceedingly muscular man, and I am satisfied that if I had put the patient under an anæsthetic and attempted the method of manipulation, I would have had much more trouble and might have done a great deal of harm.

DR. STEVENSON: I think the fact that surgeons of equal eminence and experience differ so widely is proof that cases differ. Some cases are more easily reduced by one method, other cases

can be reduced by another and by that alone. Dr. Murdoch's idea of dislocation taking place at the lower part of the acetabulum would seem to coincide with my experience in reducing them. They seem to return at that part of the acetabulum. A gentleman invited me to go with him to witness the reduction of a dislocated hip by the pulley. He said his brother had seen the case about six o'clock in the morning, and made a very continuous effort at reduction, and had failed, and he had asked me to accompany him. There had been an unsuccessful attempt made for two hours to reduce the dislocation, and it was concluded that it was impossible to reduce it without pulleys. I took hold of the limb, which was rigidly fixed; it would not go in, it would not go out. I asked the doctor if he had any objection to my trying to reduce it by manipulation. None at all. So I flexed the foot on the thigh, flexed the thigh well up on the abdomen, carried it across the body, carried it down and straightened it out, and the head of the bone slipped into place. This case was not etherized. We had just come in and this was done preparatory to commencing the operation with pulleys. I saw another case in which the femur was dislocated, the leg was thrown across the other limb. I reduced that in the same way. That was done without any anæsthetic. All cases could not be reduced in this way; I do not pretend to the skill in surgical operations that I know my friend Dr. Murdoch has. His experience is much greater than mine. I saw a case while practicing in Westmoreland county in which three or four doctors worked an hour and a half, effecting the reduction by means of extension and counter extension, and that was twenty-five years ago, before this method of manipulation was well understood. I have no doubt that in all these dislocations it is the ligament of the hip-joint that holds the limb rigidly fixed in its place. It is not so much the muscles as the ligament. Now, if the head can be made to retrace the path that it took in getting into the false position, I think there is no injury done to the ligament. I think there is no injury done to the joint. The idea of manipulation is not force; it is handling, coaxing—taking the thigh and so handling it as to make the head of the bone retrace the course it took in passing into the position in which we find it.

I cannot conceive that manipulation done cautiously and carefully can do any particular injury to the hip joint, but I can conceive that a man, or two or three men, pulling with vigor and violence, and using counter force may do great injury to a joint. I would feel disposed, from the experience I have had, to try the manipulation first. If it fail, then resort to something else.

DR. KOENIG: My experience in dislocation is

rather limited, but it goes to show that some cases are reduced readily by one method while others apparently are very easily reduced by another. While resident at the West Pennsylvania hospital, a case of dislocation of the femur was brought in, and being very anxious to try my hand at what, if I remember aright, I had never seen done before, I, together with the other resident, then serving with me, attempted to reduce that dislocation by manipulation under ether. The first attempt I made was unsuccessful, but the second one, much to my surprise, was attended with success with the use of but little force. Lately a dislocation of the shoulder presented itself at the Dispensary, and I attempted to reduce it by extension, possibly not quite after the easy method which has been detailed by Dr. Buchanan; reduction, however, proved unsuccessful to me. But in the hands of one of my colleagues it was easily accomplished.

DR. MURDOCH: I do not claim to have greater experience in the dislocation of the hip than others, though I have seen a good many dislocations. One of the first cases I ever saw, was in the army of the Potomac, where a powerful teamster had dislocated his femur, and where there were probably three hundred surgeons present, and an effort had been made by manipulation to reduce it for a couple of hours before I happened to join the company. When I got there, the patient was thoroughly anæsthetized. By very slight effort, I took hold of it and it went back into the joint. I received quite an ovation. I believe as Dr. Stevenson says, that the majority of surgeons have until recently thought the method of manipulation should always be tried first, and that has been the case at the West Pennsylvania hospital, and the resort to manipulation has usually been successful. The rule is that success is reached. But as I say we have found seven cases there in which we failed, and which were very readily reduced by the method of extension and counter-extension. Dr. Stevenson says he cannot conceive how a man can do much injury in manipulation. I give him cases of four fractures of the neck of the femur. I think it does not take much power of imagination to see how this powerful lever may break the bone. The point I desire to make is, that the amount of extension which can be made by the unaided hands should be tried first. I am beginning to believe that it is the proper course and that much damage may be saved by such a rule.

DR. MCCANN: I agree with Dr. Murdoch in the main. From one part of his remarks I must dissent; that is, that dislocation does not occur at any other place than at the lower and anterior portion of the acetabulum. I have had, in my experience, an example in which the capsular ligament was torn anteriorly to the outer side in

a case of dislocation, a case in which the patient died shortly after an accident and in which, after his death, effort was made to reduce the dislocation, which was effected by manipulation. I think that in the majority of cases it is wise to resort to extension in trying to reduce a dislocation, but I look with horror upon the pulleys, and have never resorted to them. I have seen them used with a patient under the influence of an anæsthetic, and have seen an awful amount of force used to put the head back into its normal position—more force than I have seen used in manipulation. I have seen some of the cases to which Dr. Murdoch refers. I admit there are cases where this is the proper method, and it may be proper to resort to it always, but to rely upon or go back to the old method of extension is a step backward. Now, as to manipulation, whenever that degree of force is used which will fracture the femur, it is improper. There should be no force used. The weight of the limb guided by the hand should put it in.

DR. MURDOCH: I would like to say to Dr. McCann when he speaks about going back to extension that those gentlemen who think manipulation is a modern method do not know history. The method of manipulation was used by Hippocrates. It has had advocates all the way down the ages from time to time, has been used and abandoned. Manipulation is the older method of the two. Sir Astley Cooper's method of reducing a dislocation was to suspend his patient by the dislocated limb to the branch of a tree, and if this was not successful, the surgeon might add his own weight. Now I hope I have not been understood as advocating the use of pulleys or any other powerful mechanical means. I have been careful to say that such extension should be made by the unaided hands.

DR. McCANN: This morning I had to reduce an old dislocation of the shoulder, which had been out of place for seven weeks. It is a curious fact that men will overlook dislocations of the shoulder joint. Many physicians will not take the trouble to anesthetize patients and to employ the well-known rules to establish the diagnosis. It is my opinion that the old dislocation is not a safe thing to deal with, because of adhesions which fix the head of the bone in the new position. Adhesions are liable to implicate the artery and vein and nerves. Manipulation then in an effort to reduce such a dislocation is liable to be followed by serious accidents. Injury to artery, vein and nerves may happen. Then there is another thing; the binding down the head of the bone may be so firm that unwonted and unusual efforts to reduce the dislocation, to force the head of the bone back into its normal position results in a fracture of the bone itself. These are the dangers. The method which I pursue is first to endeavor to loosen the head of the bone thoroughly

from adhesions by passive motion; to break down the adhesions by moving the arm in all directions until you feel that everything is loose. This will require several minutes, five or ten or more minutes may be thus consumed. Then I begin the reduction proper, usually by drawing the arm directly upward in a line with the body. By this method I have succeeded in reducing dislocations, six, seven, twelve and sixteen weeks old. I have never had any accident.

DR. BEATTY: I understood Dr. McCann to say the physician would not take the trouble to make the necessary examination. I would ask whether he would advise that the patient be put under an anæsthetic so as to complete examination in a dislocation of the shoulder?

DR. McCANN: I would simply say that when you are in doubt, it is always a good plan to make certain; it is always a good plan to call in some friend as counsel, anesthetize the patient, make yourself sure that you have a dislocation or that you have not. I think this is safe practice and I believe it proper it should be pursued in every case of injury of the joint in which there is doubt.

DR. BEATTY: I explain why I made this inquiry. A short time ago I was called to see an aged lady who was very fleshy about the shoulder and had all the characteristic symptoms of dislocation. She was able to put her hand upon her opposite shoulder, and she could do many other things that led me to suppose that she had not a dislocation of the shoulder, and being an aged woman, I seriously thought we had better let her alone. She was so fleshy that I could not find the head of the bone. I concluded that the best thing to do was to put my patient under the influence of ether and then make an examination. I had the assistance of a nurse, got the old lady under the influence, made the examination; the thing slipped in and the dislocation almost reduced itself. Had I not etherized my patient she would probably have gone with that shoulder dislocated the rest of her days.

DR. RIGGS: It occurs to me that a very frequent cause of overlooking dislocation of the shoulder joint is the statement of the patient. That has been brought forcibly to my mind twice. Once a miller had his arm caught in the belting of his mill. He paid no attention to it, being subject to muscular rheumatism; he went to the office of a neighboring physician and told him he had a severe attack of rheumatism in the arm, and would like him to inject morphia. The physician made no examination, injected the morphia, and gave the man something for rheumatism. The man went around with his arm in this shape for months. This was in March. About the middle of August I was passing his house one day and he asked me to stop and look at his arm. I went in. I had seen him frequently on the street and always in that position, he never seemed to move his arm.

I thought he must be suffering from a dislocation, and asked him to allow me to examine the joint. I did not give him ether in the reduction of it. I told him we would first break up the adhesions if he was willing to stand it. He agreed to this, and after the adhesions were broken up, the dislocation was reduced very readily. I did not give an anæsthetic. Another case, a man fell from a moving train, falling on his shoulder and simply stated to the physician that he had fallen off the train and struck his shoulder. The physician did not look for a dislocation. It was allowed to go for about ten days. So that I think it is always necessary to inquire carefully, and in some cases to use an anæsthetic when in doubt.

SPECIAL CORRESPONDENCE.

Shall The Journal be Removed to Washington?

To the Editor.—As a member of the Association I oppose the removal of THE JOURNAL to Washington City. I cannot see any advantage to be gained from the more central point—Chicago.

If a removal is demanded, and the convenience of the members is to be considered, why not seek a central point, and establish headquarters at St. Louis, Mo?

JNO. W. TRADER, M.D.

Sedalia, Mo., Jan. 26, 1891.

To the Editor.—Views of Dr. W. F. Rochelle, in No. 4, January 24, endorsed. Keep THE JOURNAL in Chicago. Nothing to be gained by the change.

T. R. LUFF, M.D.

Cincinnati, O., Jan. 27, 1891.

To the Editor.—The pride of the American physician consists in his success, his success in his advantages, and his advantages of reading THE JOURNAL at an early date will be greater if allowed to remain in Chicago than if taken to Washington. I mean the M.D.'s of the West.

J. H. LYON, M.D.

Roslyn, Washington, Jan. 22, 1891.

To the Editor.—If I remember rightly, the proposition was made, at a recent meeting of the Association, to select a permanent location for our annual meetings; I do not remember decision, but if in the affirmative, I certainly deem said place to be the proper one at which to publish THE JOURNAL, otherwise, I cannot see any benefit, pecuniary or other, to be derived by moving from Chicago. I therefore vote that no change be made.

A. PARKER CHAMPLIN, M.D.

Biloxi, Miss., Jan. 27, 1891.

To the Editor.—I prefer that THE JOURNAL should stay where it is; for it is in the midst of a thriving, stirring medical people, and it is all the time growing fuller and richer in practical ideas. To be sure we have a great body of cold science in the East, but it needs to come to life and be clothed for practical work. Now the free, warm spirit of the great West is just the thing to move upon the medical bones of the East to cause them to stand up and give an efficiency to American practice that beats the world; for with our constitutional make-up, with proper training, and with the most wide-awake journals in our hand, we ought to be the ablest bedside

practitioners beneath the sun, and if we are not we disgrace the Yankee name.

E. CHENEY, M.D.

65 Chandler St., Boston, Mass., Jan. 27, 1891.

To the Editor.—Please record my vote in favor of continuing the publication of this journal in Chicago.

J. G. BEARDS, M.D.

101 W. Madison St., Chicago, January 30, 1891.

To the Editor.—Please register my vote against moving THE JOURNAL to Washington or anywhere else.

F. E. YOUNG, M.D.

Shreveport, La., January 29, 1891.

To the Editor.—In the last issue Dr. Solis-Cohen considers the matter of the removal of THE JOURNAL. A careful perusal of his letter shows it to be a "mongrel mixture of argument and assertion, seasoned with a few facts."

Dr. Cohen in his letter starts with the question, where can THE JOURNAL be best edited and best serve the interests of the Association. Then he proceeds to find fault with the management of THE JOURNAL, stating that it has identified itself with local interests, that it has not attracted the work of the best men, that it has not been sufficiently careful in rejecting poor papers, and finally, that its abstracts and selections have not been up to standard. The editorial department he considers to have been one of the strongest features of THE JOURNAL.

With this sufficiently perspicuous statement of the shortcomings of THE JOURNAL, the writer proceeds to find a cause for it in the fact that the home of THE JOURNAL has been in Chicago. That it must be due to some evil and malign influences that surround the publication in its present location, the doctor thinks is attested by the fact that the *personnel* of the editorial staff could not be better, and therefore it must be due to local restrictions. It should be gratifying to the profession in Chicago, as misery is said to love company, to know that the same peculiar miasm is present in Philadelphia, New York, Boston and Baltimore. We cannot refrain from congratulating the profession of Washington upon their singular exemption from this kind of infection. We had supposed that there were some fairly representative journals published in this country, notably the *American Journal of the Medical Sciences*, but it is only necessary to read Dr. Cohen's letter to be convinced that its influence is purely local, and that it would have had a wide and grand success had it only been removed to Washington.

Granting, for the sake of argument, that the doctor's strictures regarding the management of THE JOURNAL are true, what guarantee have we that if it is moved, local influences or the advancement of individual interests will not dictate its conduct in its new home? Have the profession of Washington alone those self-effacing qualities that will allow them to remain invisible while they conduct THE JOURNAL into higher and ever widening plains of usefulness? What covenant will they enter into? What bond will they give that such shall come to pass?

The reasons in favor of Washington are delightfully simple. The removal would immediately relieve local influences, and this would raise the standard; this improvement would attract the best minds, and so all would go on in ever increasing grandeur. As near as we can analyze Dr. Cohen's statement, there seems to be in Washington a great, intangible, psychic entity, that has its being as an incorporeal body working in and for the good of the but not of it, for they are of the earth, and this is of the spiritual and invisible. For convenience we may name this influence, the *Great Good*, just as we may call that other equally intangible thing existing in Chicago, New York, Philadelphia and Baltimore, the *Great Evil*.

In conclusion, Mr. Editor, I would like to say that I regard the removal of the Association storm-centre from Chicago to Washington as a simple change, and not in any sense as a solution of whatever real or imaginary ills may affect THE JOURNAL.

If THE JOURNAL is not up to what it could be made, let the Trustees see to it that it is improved. Nothing will be gained by a simple transfer of editing, printing, press-work or binding to either Washington, Oshkosh or Kalamazoo.

HAROLD N. MOYER, M.D.

Chicago, January 31, 1891.

To the Editor:—Permit me through the columns of your journal to ask our friend Dr. Solomon Solis-Cohen to please verify his assertion under No. 1, to point out the Vol., No. and page of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION in which said journal has debased itself either in its editorial or news columns as he alleges it to have done.

While the doctor is on the stand we would be glad to have him enlighten the thousands of readers of THE JOURNAL on his 2nd proposition and tell us in what respect Chicago debars the best scientific men in the country from sending the best productions they can produce to THE JOURNAL of the National Association, or in what respect *Washington* would have any greater magnetic attraction for these articles than the great metropolis of the west. Certainly Washington has never shown any great distinction in the literary field, either in the past or present; surely not in the newspaper, notwithstanding it is the Capital, on which the doctor puts so much stress in his remarks.

We will be glad to have the doctor, while he has the stand, explain to us in what respect *Washington* would facilitate the ejection of the *worthless* papers, any more than Chicago? To say that THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION has not, and does not present anything new to its readers is a severe criticism on the doctor himself, who has been a contributor to its columns in the past, saying nothing of the work of such men as Senn, Parkes, Fenger, Conner, McGraw, Van Deever, Wood, and scores of other eminent American investigators and writers who have contributed to its columns from time to time some of the ablest articles of the age.

In what respect, pray tell us, will the removal of THE JOURNAL to Washington improve its abstract column? Certainly a useless expenditure of money for its removal, together with the loss of advertising patronage by its removal would not in any manner aid in the securing of better abstracts or a higher class of reviews.

In reading No. 5, one would imagine that Washington was the only place where "well informed and thoughtful editorial comments upon questions of importance" could be manufactured; if this is true it does seem strange that Washington has never been, and is not now a medical centre in any sense of the word.

In regard to No. 1 of his second series; if the doctor had said that Washington belonged to the political parties alike, and the temptation to debase statesmanship by rings and factions for personal interests was rife in that city, he would have hit the nail on the head exactly. Surely it is a trifle hazardous to the real interests of THE JOURNAL to have it surrounded with an atmosphere that is so impregnated with political strife, and one that is so frequently disturbed by multitudes of ambitious whirlwinds that are liable to affect even a great National medical journal.

In No. 2 he refers to the treasures of the Surgeon-General's Library in the National Museum; very good; but the new library of Chicago, when completed, will excel the Surgeon-General's Library for *real value* as far as lightning beats a sheep; while the National Museum is not of a great deal of benefit for the production of origi-

inal thought, or investigation such as the doctor has dwelt on so much in his caustic letter.

In No. 3 may I be permitted to ask him, and that with all due respect to the medical profession in Washington, to point me out one single member of the same who has distinguished himself by his original investigation, of original subjects, and thereby produced something NEW (such as he claims should only enter the columns of THE JOURNAL) for the enlightenment and benefit of the profession?

In reply to No. 4 it is difficult to see, under all the circumstances and present evidence, how the removal of THE JOURNAL from the second LARGEST city of our country, to one scarcely ONE-FIFTH as large, would raise the editorial status of the same, or be any greater incentive to attract able papers from the best members of our profession; and hence we would be glad to have the doctor proceed to explain the philosophy of this kind of logic.

Then, in No. 5, he goes on to say that only by *concentration* the best work can be done, and yet in his previous breath he advocates the removal of THE JOURNAL from the great western metropolis which is the *largest* railroad centre in the world, to a diminutive city as compared with Chicago in any particular, with only three railroads, and then claims that that is *concentration*, and is conducive to medical elevation; especially when *two-thirds* of all the members of our Association live WEST of the Allegheny mountains, and only *one-third* EAST of the Appalachian range.

Now, doctor, this is a strictly business transaction, and should be regarded as such by all who are interested in the *welfare* of THE JOURNAL, and I will now close by asking you, if Washington is such a great centre, why business men, wholesale dealers, manufacturing establishments, railroads and commerce in general, are not centred there? If other business interests have not found that a profitable centre for them, and newspapers and magazines have not flourished there, how can you expect our National Medical Journal to fare any better?

Let us hear from you, doctor, and let us have a rational solution of this question, in a logical manner.

R. HARVEY REED, M.D.

Mansfield, O., Jan. 31, 1891.

MISCELLANY.

LIST OF PERMANENT MEMBERS.—The names of Dr. J. H. Lyon, Roslyn, Wash., and Dr. Karl von Ruck, Ashfield, N. C., were omitted from the List of Members in our December issue.

Official List of Changes in the Medical Corps of the U. S. Navy, for the Week Ending January 31, 1891.

Asst. Surgeon R. P. Crandall, ordered to examination preliminary to promotion.

P. A. Surgeon T. A. Berryhill, detached from the "McArthur" and wait orders to the "Marion."

Surgeon W. H. Jones, detached from the "Swatara," proceed home and granted six weeks' leave.

Official List of Changes of Stations and Duties of Medical Officers of the U. S. Marine-Hospital Service, for the Four Weeks Ending January 21, 1891.

Surgeon P. H. Bailhache, granted leave of absence for seven days, January 12, 1891.

Surgeon George Purviance, to proceed to Pittsburgh and Erie, Pa., Cleveland and Toledo, O., Detroit, Mich., and Buffalo, N. Y., as Inspector. December 29, 1890.

P. A. Surgeon P. M. Carrington, granted leave of absence for seven days, January 16, 1891.

Asst. Surgeon H. D. Geddings, to report in person to the Supervising Surgeon-General, January 16, 1891. Detailed for special duty, post of Georgetown, D. C., January 16, 1891.

Asst. Surgeon W. G. Simpson, to proceed to New Orleans, La., for temporary duty. January 6, 1891.

ANEURISMAL TUMOR OF THE RIGHT
ALVEOLAR PROCESS AND VAULT
OF THE MOUTH TREATED BY
INJECTION.

BY JOHN S. MARSHALL, M.D.,

PROFESSOR OF ORAL SURGERY, UNIVERSITY DENTAL COLLEGE,
VISITING ORAL SURGEON TO ST. LUKE'S EFIE HOSPITAL,
AND MERCY HOSPITAL, CHICAGO, ILL.

Mr. C. B. H., of Chicago, American, aged 26 years, occupation traveling salesman, was referred to me December 26, 1888, for counsel and treatment by Dr. M. Stout, of Chicago, with the following history: Some eighteen or twenty months previous to this examination the gentleman had submitted to the extraction of all his superior teeth, except the central incisors. The operation was performed under nitrous oxide gas; the mouth was badly bruised and lacerated on account of the difficulty in extracting the teeth. A few weeks afterwards he noticed a swelling upon the inner side of the right alveolar ridge, which continued to enlarge as the months went by, and prevented the making of the artificial denture, which he was anxious to have placed in his mouth. There was no pain or uncomfortable feeling about the tumor, except when engaged in vigorous exercise; at such times pulsation in the part would become very marked and disagreeable.

According to his own statement he had "consulted several dentists (?) in relation to the character of the swelling; some did not know what it was; one said it was an accumulation of pus, another that it was a 'watery tumor,' and a third that it was a 'wind,' and asked the privilege of letting it out." This very kind offer, however, was declined, much to the permanent benefit and longevity of our patient.

Examination of the mouth revealed the superior teeth all gone except the central incisors, and a pulsating tumor about one and one half inches in length, by one inch in width, egg-shaped in form, with the small end pointing forwards, and occupying the right side of the vault of the mouth, from the outer wall of the alveolar process, to the median line, and from the tuberosity

of the maxilla forward to a line drawn through the cuspid region.

In character it was soft, fluctuating, compressible and with very marked pulsation. In color it was slightly deeper in tint than the surrounding mucous membrane. Upon puncturing it with an exploring needle, a jet of arterial blood followed its withdrawal, and continued to spurt for about half a minute, when the hemorrhage ceased.

The diagnosis was aneurismal tumor of the posterior palatine artery, with possible anastomosis with some branch of the superior maxillary artery, the result of injury in the extraction of the teeth. An operation was advised, and the gentleman agreed to report in about two months. Cast No. 1 is a copy of the upper jaw at this

CAST 1

period. Business engagements prevented his keeping this appointment, and when he next called to arrange for the operation, I was out of town on my summer vacation. He was also on vacation, and could not wait my return, and therefore sought other advice.

October 10, 1889, I saw him again, at which time he gave me the following additional history: That in July he had been operated upon for the removal of the tumor and had nearly died under the operation, from hemorrhage, and was afterwards confined to his bed for two months, with blood-poisoning.

The cast which I now show you, No. 2, is a copy of his upper jaw taken on December 17, 1889, a few days before I operated upon him.

You will see by this that there was no improvement in the condition as described in the examination made a year previously, but that the tumor was larger.

CASE 2.

The surgical treatment of aneurisms is by ligating the artery near the cardiac or distal extremity of the sac, or both; by compression either instrumental or digital; by the introduction of foreign substances into the sac, like catgut, horse hair or fine iron or silver wire; by manipulation; by acupuncture; by galvanopuncture; by the injection of coagulating fluids, and in the case of small anastomosing or cirroid aneurisms, by dissection.

The particular method adopted being controlled by the character and location of the aneurisms, the chances of danger to life, the possibilities of a cure, and the individual preferences of the operator. In all such cases, as are susceptible of ligation, this is by far the most satisfactory surgical procedure. But in those which from their location cannot be reached by this method some one of the other means may be employed.

In the case under consideration treatment by ligation, compression, manipulation, acupuncture or dissection was out of the question; the means at our command were therefore limited to three methods: the introduction of foreign substances, like wire, etc., galvanopuncture, and injection.

Treatment by the introduction of foreign substances, either animal or metallic, seemed slow and unsatisfactory, and gave little hope of success, for I had been unable to find a single case on record of a cure by this means, while the dangers from embolism were great.

Galvano-puncture was considered too tedious an operation, from the fact that several would most likely be required to effect a cure, while the dangers from embolism and from hemorrhage as a result of sloughing at the points of puncture, made it seem extremely hazardous. I therefore decided to treat the case by injection, though this method is by no means free from the dangers already enumerated. The injection method in

aneurisms of large arteries is generally considered positively unsafe; and in those occurring in terminal branches of arteries, it has not met with much favor by the profession, chiefly for the reason that several fatal results from embolism were recorded soon after its introduction, and thus deterred many from giving it a trial in those cases which might be considered favorable.

The danger of this method in aneurisms connected with small arteries, it seems to me are not in the method itself, but in the kind, and strength of the coagulating fluids used.

The agents which have been suggested are numerous, among which are acetate of lead, acetic acid, iodine, ergotine, and the perchloride of iron. The perchloride has generally been given the preference, used in small quantities and weak solutions of 1 to 2 per cent.

The injection of solutions in the above quantity and strength, produce very slow coagulation, and when the clot is formed, it is soft and friable, as a consequence it is easily broken up, and floated away, giving rise to embolism in remote parts of the circulatory system, with all its accompanying dangers. The dangers in acupuncture, galvano puncture, and the introduction of foreign substances into the sac, are for the same reasons equally great.

The perchloride of iron is a vigorous coagulant, and quite escharotic and antiseptic when used in full strength. A 1 or 2 per cent. solution is very mild in its styptic and coagulant qualities; is not escharotic, and has no value as an antiseptic.

What is needed in the treatment of this class of cases, is to produce a firm clot, instantaneously if possible, and to maintain it in an aseptic condition, without the dangers of sloughing or hemorrhage.

In the perchloride solution of proper strength it would seem that we had all these requirements.

By the production of instantaneous and complete coagulation of the blood in aneurisms of this class and nevi, the dangers from embolism in remote parts of the body, would seem to be entirely overcome, and thus one great objection to this method removed; at least this was my thought upon the matter, and I determined to try it in this case, in preference to the other methods which might have been chosen.

In order to produce a complete and firm coagulum, instantaneously, it would be necessary to use a solution of much greater strength, than had been previously recommended.

From the size of the tumor, I concluded that in all probability it contained from one to one and a half ounces of blood, and that the introduction of five minims of the following solution, perchloride of iron one part, water four parts, would not be sufficiently escharotic to do any mischief, when diluted with this quantity of blood.

On December 22, 1889, I injected into the tumor five minims of the above solution, which produced instantaneous coagulation, making the tumor feel as firm as a fibroma; considerable pain followed the injection, but this gradually subsided after a few minutes, but he complained for some hours of a strange fullness of the right side of the head. On withdrawing the hypodermic needle, a little oozing occurred which immediately discolored the mucous membrane for a little distance around the puncture made by the needle. No other unpleasant symptoms followed.

December 28, the mucous membrane, at the point punctured by the needle, sloughed, leaving an opening into the sac, about the size of a silver half dime, exposing the hard clot. There was not the slightest hæmorrhage, but considerable anxiety was felt, for fear of such an occurrence.

Tiersch's antiseptic solution was constantly used as a mouth wash during the whole progress of the case, and after the slough occurred, the sac was syringed with the same solution at short intervals, day and night.

December 31, the clot was broken up and removed, when it was found that the aneurism also occupied the antrum of highmore, and had produced absorption of the palatine process, of the superior maxillary bone, and the nasal wall of the antrum, leaving a large opening into the nasal fossa. The case progressed without a single drawback from this time onward. The opening into the antrum and floor of the nasal fossa, finally closed. There has been no recurrence, and the patient considers himself perfectly well.

CAST 3.

Cast No. 3, shows his present condition.

Remarks.—The sloughing of the mucous membrane at the point of puncture, proves that the strength of the solution was too great for absolute safety, and should I be called upon to treat another case of this class, I should not feel warranted in using a solution stronger than one in six or eight parts of water. This, I think, would produce the desired results, without the dangers of causing a slough, and possible hæmorrhage.

COFFEE, ITS USE AND ABUSE.

By E. N. LOVE, M.D.

OF ST. LOUIS.

I shall not attempt to present a history of the coffee plant, but rather give a few of the virtues it possesses, and draw attention to the fact that the commonplace is often overlooked in our desire to discover that which is new, striking and sensational. I recall a remark that I heard made a year or two ago by a very worthy but somewhat censorious member of our profession, to the effect that he did not propose to attempt to address the profession unless he had something absolutely original to offer. In this connection, I venture this thought: that which is good and true will bear repetition, and it is rarely original.

In Southern Abyssinia the coffee plant grows wild in profusion, and has been in use from very ancient times. The name is probably taken from Koffa, the name of a district south of Abyssinia. The coffee-producing belt of the world lies between latitudes 25 north and 30 south. The coffee plant does not thrive where the temperature is below 55°, hence the cultivation is chiefly in the tropics, the principal countries being Brazil, Java, Ceylon, Abyssinia, West Indies, Central America, Peru, Bolivia, etc. It would be interesting to present a succinct history of the plant and the gradual development of its virtues during ages past, but that is not the purpose of this short paper. The fact that there is imported annually into the United States nearly 800,000,000 lbs. of coffee, indicates its importance as an article of diet. It is an odd and interesting fact that the active principle of all the domestic beverages of the world is practically the same, viz.: caffeine in coffee, theine in tea, theobroma in cocoa.

The best coffee of commerce is Mocha, the next in order being Java. A mixture of equal parts of the two is really the best and most agreeable in flavor. The coffee, in order to be in form for use, must be roasted, and much depends upon its treatment. In order to secure an infusion of roasted coffee in its perfection, it should be boiled in a closed vessel carefully, so as not to be overdone, only the amount necessary to be immediately used; by this means the rich aroma of the coffee, which gives it its most delicious flavor, is preserved.

I venture the opinion, that there is no beverage on the earth to day which, used in moderation, expresses more comfort, contentment and calmness to the cerebral centres, than coffee; but in

excess, it is undoubtedly most dangerous. I doubt if the victims of alcoholic excess are as numerous as those who over-indulge in coffee. Alcohol has two advantages in that it is a food and its excessive use is disgraceful. The infusion of coffee in proper quantities aids digestion, and is a safe cerebro-spinal stimulant which is not followed by perceptible reaction. Liebig drew attention first to the fact that this beverage contains the elements which stimulate the flow of bile. It is a decided laxative, a pronounced diuretic. The fact that the coffee belt of the world is also the "bilious belt" and the malarial belt, as well as the field where noxious germs and suppurative processes do most abound, is evidence of the fitness of things. No one better than the denizens of the hot regions of the world, know the value of coffee to open up the secretions which have been checked by excessive heat or the malarial influence. They know well, and have known for centuries, that which has recently been receiving much attention in the medical world, particularly in Germany, viz.: the antiseptic properties of coffee.

Appropos to this point, Carl Luderitz, in the *Zeitschrift für Hygiene*, has recently presented an interesting report concerning the influence of infusions of coffee on microorganisms, of which the *New York Medical Journal* of May 3, 1890, presents a brief epitome as follows:

Luderitz details a careful series of experiments in which he determined the influence of coffee infusions of different strength (varying from 10 to 30 per cent.) upon the growth of various forms of pathogenic and non pathogenic microorganisms. The coffee used in these experiments was roasted Java, and the infusion was made by adding from ten to thirty parts of coffee by weight to seventy or ninety parts of boiling hot water. The coffee, freshly roasted and ground fine, was covered with boiling water, and the infusion thus prepared was placed in a closed flask in a water-bath for about ten minutes, and was then filtered through a sterilized filter. This infusion was used in part for making gelatin and in part directly. Where nutrient gelatin was made with this as a menstruum, it was inoculated with various forms of fungi and other microorganisms, to determine the possibility of their growth in such a medium. In other cases the organisms were added directly to the infusion of varying strength, and after different periods of time inoculations were made from the infusions into other nutrient media. Luderitz found that the forms of fungi experimented with showed more or less growth in the coffee gelatin, but the abundance of growth was in many cases distinctly less than in other media. The other microorganisms he used for his experiments were the staphylococcus pyogenes aureus, the streptococcus erysipellatus, the typhoid bacillus, the spirillum of cholera Asiatica, the bacillus anthracis, the bacillus prodigiosus and the proteus vulgaris. All these forms of microorganisms were greatly influenced in their life and growth by exposure to the infusions of coffee, but some were far more susceptible than others. The bacillus prodigiosus was totally destroyed only after exposure in a 10 per cent. infusion for four days, or in a 30 per cent. infusion for one day. The typhoid bacillus was completely destroyed after exposure in a 5 per cent. infusion for three days, in a 10 per cent. infusion for from one to three days, or in a 30 per cent. infusion for one or two days. The proteus vulgaris was killed after an exposure for four days in a 10 per cent.

infusion. The staphylococcus pyogenes aureus was destroyed only after an exposure for six days in a 10 per cent. infusion, and for three days in a 30 per cent. infusion. The streptococcus erysipellatus was destroyed after an exposure of one day in a 10 per cent. infusion. The bacillus of Asiatic cholera was destroyed in a 1 per cent. infusion after seven hours' exposure, in a 5 per cent. infusion after four hours, and in a 30 per cent. infusion after two hours. The bacillus anthracis was destroyed in a 10 per cent. infusion after three hours, and in a 30 per cent. infusion after two hours. The spores of the anthrax bacillus were only destroyed, for the most part, after three weeks' exposure in 20 and 30 per cent. infusions.

Aside from these experiments, others were made with decomposing meat bouillon, which was swarming with various forms of microorganisms. The results obtained from these showed that while the viability of the spores contained in the fluid was greatly diminished after a short exposure, it was not completely destroyed until after an exposure of many days. The cholera spirillum was by far the most susceptible of the organisms used in the experiments, and next to it stood the anthrax bacillus without spores.

At this moment a recollection of the fact comes to my mind that Dr. C. H. Hughes, of St. Louis, not less than fifteen years ago, drew attention to the antiseptic properties of coffee. Since, however, the grand moguls of Germania have taken snuff on the coffee question, undoubtedly the Germaniacs of science on this side of the Atlantic will all sneeze simultaneously.

The fact that coffee blunts sensation and increases secretion, would suggest that we educate the laity in the direction of at once giving the victims of accident a good cup of hot coffee, rather than the usually over-stiff whisky toddy, which in many cases, given in excess as it is, places the individual not only in an unfavorable condition physically, but also renders him liable to the charge later, from those not familiar with the facts, of having been injured on account of drunkenness. I recall the case of a young lady horseback riding in the suburbs of St. Louis some years ago, thrown from her horse, leg fractured, taken in by good Samaritans close at hand. On being summoned, I at once responded, and recognized the victim as being one of the "swellest set" of St. Louis' best society. I placed the patient in my carriage and removed her to her home. She was dead drunk, and before we reached her home, there was not a space three inches square in the carriage which was not covered with that which had, prior to the accident, been part of the contents of her stomach. Those unfamiliar with the fact of her having been filled to the brim with whisky by the good Samaritans who took her in, might have seriously reflected upon her character. A good cup of black coffee would have done her better service and risked her character less. So to the public we would say, give to those who have been injured a good cup of coffee in the name of humanity, but no whisky.

The custom which prevails in New Orleans, and generally through the South, of taking a cup of strong black coffee in the early morning, is an

intelligent one. The people of those malarious regions have long since demonstrated the fact that the custom referred to is of great advantage as a prophylactic. The individual experience of the writer for five or six years past, is strongly in favor of the taking of a liberal cup of black coffee without cream or sugar, sandwiched in between two glasses of hot water, a few minutes before rising every morning, at least one hour before breakfast. The various secretions are stimulated; the nervous force is aroused; an hour later, a hearty meal is enjoyed and the day's labor is commenced favorably, no matter how the duties of the day and night preceding may have drawn upon the physique. Another cup of coffee at four in the afternoon is sufficient to keep the energies unflagged for many hours thereafter. Taken in this manner, the full effect is secured; the stimulant devotes itself strictly to business, none of it is lost, and if the proper diet be taken at the proper times between (and the ideal diet for those who make large drafts upon their nervous systems and expect to have them honored, is hot milk) if the above regimen be followed and accompanied by at least eight hours sleep out of every twenty-four hours, the capacity for work is almost unlimited. How many of our patients who are the victims of disease, are ever consulted as to whether they have been accustomed to the habitual use of coffee, or not? Take, for instance, typhoid fever; a long seige of suffering; a racked and wrecked nervous system; the chances largely in favor of the patient having been an habitual drinker of coffee, but whether so or not, the coffee is usually not given, though strongly indicated, for the reason that it sustains and supports weary, worn nerves, aids digestion, keeps the alimentary canal, which is swarming with germs and putrefactive material, in a more or less antiseptic condition (it has previously been shown that coffee is peculiarly destructive to the typhoid bacillus), helps to gently open the sewers of the system, being as it is a diuretic, a stimulator of the bile flow and other secretions, allays the sense of fatigue and lessens tissue waste, braces up the heart's action and raises arterial tension. We all know that to prevent a chill, nothing is superior to a cup of strong black coffee. As an antagonist to opium narcosis, strong black coffee stands preëminent. This brief and disjointed paper would be unfinished unless a reference were made to the injury likely to follow the excessive use of coffee. In excess, it disorders digestion, removes the desire for food, creates an indisposition to sleep, excites headache, vertigo, mental confusion and disturbed heart action.

In this connection I recall the case of Mrs. S., whom I was called to see in consultation some miles from St. Louis about three years ago. A mother of five children all born within eight years, one or more of them sick half the time

from the time of their birth. Mother conscientious and ever alert to her duty, suddenly taken down with heart trouble and such nervous symptoms as to apparently imperil life. Upon examination, I discovered an almost bloodless woman with a heart beating irregularly but so fast as to be almost beyond counting. A restless, hunted down expression of face and physique; no fever; an utter inability to sleep; no appetite for weeks past. The history which I soon elicited demonstrated the fact, which had been overlooked by her attendant, but which I suspected from seeing a coffee pot upon the table by the bedside, viz., that the mother in order to bear up under the burdens placed upon her, had been for six months absolutely living upon black coffee. The desire for food or ability to digest it had long since gone. The blood had become impoverished from lack of sustenance. Like the indiscreet owner of the thoroughbred roadster, she had been constantly feeding with the whip instead of oats. Her cerebro-spinal centres, the acceleratory nerves of her heart, would have soon been whipped to the point of exhaustion. Opiates and digitalis, whisky and pre-digested milk, good sleep, a check rein upon her circulatory organ, oats instead of the whip, in the form of nutrition easy to assimilate, gradually brought the patient around to a condition of health. It may not be uninteresting to state that this excellent woman, although a coffee drunkard, was a member of the local Temperance Union.

After years of extended observation and pronounced personal experience I feel justified in announcing:

1. The world has in the infusion of coffee, one of its most valuable beverages.
2. As a prompt diffusible stimulant either by the stomach or by injection into the rectum, it is in all cases of shock, preferable to alcohol.
3. It is antagonistic to malaria and specially destructive to the typhoid bacillus and cholera germ, and for this reason it is an admirable remedial agent in these conditions, both as a direct stimulant, an antiseptic and an encourager of elimination.
4. One of its chief advantages in health and disease is in the fact that it aids in the securing of that psychological satisfaction which is conducive to hope, comfort, good digestion, great power of resistance and rapid recuperation.
5. In season, it supports, tides over dangers, helps the appropriative powers of the system, whips up the flagging energies, enhances the endurance, but is in no sense a food, and for these reasons and many others, it should be used temperately, as should all of nature's benign gifts.
6. In excess, it is even more dangerous than alcohol, for it is not, like the latter, a nutrient, nor is the effect of its excessive use so apparent or unrespectable.

A STUDY OF STERILITY, ITS CAUSES AND TREATMENT.

Being an Essay which received the First Prize of the Alumni Association of the College of Physicians and Surgeons, Baltimore.

BY THOS. W. KAY, M.D.,
OF SCRANTON, PA.

(Continued from page 184.)

CAUSES.

1. *Non-production.*—Non-production of healthy ova and spermatozoa may be caused by (a) absence, non-development or malposition of the genital glands; (b) inflammatory troubles producing atrophy or destruction of those organs; (c) tumors or new growths affecting the nutrition of, or directly invading, the gland substance; and (d) all influences which affect the glands indirectly by altering the general condition of the body.

In all barren marriages where symptoms of uterine disease are not well pronounced, we should first make a microscopical examination of the spermatid fluid. This can be easily obtained by withdrawal of the organ as orgasm approaches, or by collecting the fluid, by means of a small syringe, from the vagina after the act has been completed. The best method, however, is the use of a condom during coitus.

Male.—The quantity of the seminal fluid depends on the size of the testes and the habits and physical condition of the male. Sims places the average quantity at about 2 drachms. It is not the quantity, however, but the quality, that concerns the physician, for though there may be a normal quantity of fluid discharged, the spermatozoa may be entirely absent—azoospermia.

Should there be no discharge—aspermia—it is useless to look for spermatozoa, but they may exist in large quantities and in a perfectly healthy condition when only a small quantity of fluid is discharged. Either of the above conditions may be congenital or acquired. The congenital variety, as a rule, is permanent, but the acquired form is either permanent or temporary.

(a.) In the congenital variety there is an absence or imperfect development of the testes, which prevents the production of the spermatid fluid. The absence of one testis—monorchism—is of little moment, but the absence of both testes from the scrotum—cryptorchidism—generally indicates sterility. This, though, is not always the case, for one or both testes may exist in the abdominal cavity and be in a healthy condition.

(b.) The most common cause of the acquired form is orchitis, due to external injury, mumps, gonorrhoea, syphilis, or other troubles in which an atrophy of the glandular elements is caused by the inflammatory process.

(c.) Hernia, hydrocele, varicocele, and all benign tumors disturb the nutrition of the testes by

pressure or by dragging on the blood-vessels, and thus produce atrophy. Cystic diseases, tubercle and malignant tumors destroy the testis by a direct invasion of its glandular structure.

(d.) All fevers and inflammatory or wasting diseases affect the testis temporarily by impairing the general health. The sterility due to excessive venery, masturbation, and affections of the nervous system, is usually temporary, but may become permanent through organic changes taking place in the testes. Heredity, consanguinity, and many other agencies affect the reproductive organs of the male, but in exactly the same way in which they affect those of the female. At what time senile sterility is established in the male is not definitely known, but as his development is less rapid than that of the female, so is his loss of power postponed till later in life. In temperate climates the reproductive power may be established as early as the 14th year and be maintained, in persons of robust constitutions, as late as the 70th, 80th and 90th year.

Female.—(a.) The ovaries may be, one or both, congenitally absent or imperfectly developed. The absence of one is of little importance, for the other, if healthy, is sufficient to furnish ova for impregnation.

Congenital absence or defect of both ovaries is generally accompanied by other abnormal conditions of both the internal and external organs of generation. Many interesting cases of this kind are found in all works on gynecology. Pro-lapse of the ovaries may affect their nutrition and set up inflammatory changes which result in atrophy and destruction of the Graafian follicles.

(b.) Aristotle seems to have been the first author to point out the fact that early marriages are a frequent cause of sterility, and the statistics collected by Duncan and Kisch show conclusively that not only is sterility more frequent, but the birth of the first child is postponed longer in those marriages where the woman is 15 to 19 years of age than where she is 20 to 24 years of age. This is due to inflammatory changes caused by injury during coitus or at childbirth, to imperfectly developed genital organs. The researches of Slavjansky have shown that inflammation, with subsequent atrophy of the Graafian follicles, may occur in rickets, scrofula, tuberculosis, pneumonia, typhoid fever, and all inflammatory and wasting diseases. In both acute and chronic ovaritis there may be an absorption of the follicular contents, followed by a collapse and adhesion of the follicular walls, which results in atrophy of the ovaries. It is in a different way that pelvic peritonitis acts. Here, the inflammatory products thrown out contract, and both dislocate and compress the ovaries so as to disturb their blood supply. Syphilis causes atrophy, directly, by affecting the ovaries, and indirectly, by setting up peritoneal inflammation.

(c.) All new growths of the ovaries—cystic (follicular, multilocular, dermoid, papillary and myxo polypoid), and solid (papilloma, fibroma, fibromyxoma, sarcoma, carcinoma and enchondroma) induce sterility by destroying the structure of or producing atrophy of the ovaries. As long, however, as a healthy portion of the ovary remains, conception is possible. Schröder took advantage of this in operating, and would always leave a piece of healthy ovary when it was possible. The possibility of spayed sows getting with pig has long been known to stock-raisers, and I have seen several examples of it in my own neighborhood. Schatz reported a case where a young woman of 20, on whom double ovariectomy had been performed, conceived. In all of these cases a part of the ovary must have been left, or it may be that a supernumerary or accessory ovary existed, as in cases reported by Biegel, Klebs, Ols-hausen, Winckel and others. In the female, as in the male, varicocele may exist, about the organs of Rosenmüller, and produce atrophic changes by disturbing the circulation of the ovaries, but this affection is exceedingly rare.

(d.) In females suffering from diabetes, anæmia, chlorosis, and chronic affections of the nervous system, conception is rare, because of lack of sufficient energy to produce healthy ova. It is probably in the same way that the excessive or long continued use of alcoholic stimulants, opiates and other drugs prevent conception. The causative influence of obesity in producing sterility is very doubtful. It does not prevent the production of healthy ova, but indicates a lack of vigor and a sluggish condition of the general system unfavorable to ovulation. The ova are discharged periodically about once a month, and it is about that time that impregnation is most apt to occur. Of 248 cases, in which the time of copulation was definitely known, Hasler found that conception took place in 86 per cent. during the first ten days after the cessation of the menstrual flow. Capellman advises sexual abstinence for fourteen days after the cessation of, and three or four days before the appearance of the menstrual flow, if one desires to avoid conception. The Jews, the most prolific of all people, allow five days for the menstrual flow and to this add seven days, making in all twelve days, from the first appearance of the menses, during which coitus is forbidden.

The season of the year also affects conception, and we find it occurring much more readily in spring and summer than in autumn and winter. Haycroft, who has carefully studied the subject, finds that in Scotland the number of women who conceive increases with the rise of temperature.

The quantity and quality of the food materially affects conception, it being a well known fact that more children are born during years of plenty than during famines. Women in moderate circumstances, however, are more prolific than those

who live in luxury and idleness. Hensen points out the fact that melons and cucumbers are more productive when raised in the shade and furnished with moisture than when exposed to the sun and a dry heat, and argues that women are affected, to a certain extent, by the same causes.

We saw that this was so when speaking of food and temperatures, and it is even more noticeable in the lower animals than it is in man. Pigeons are much more prolific when well housed and liberally fed than when they are allowed to look out for themselves. Indoor confinement or change of long established habits will tend to cause sterility in both the lower animals and in man. All showmen know that wild animals are remarkably unproductive when deprived of their accustomed freedom.

In France it has been shown that of eggs laid by uncouped hens only 20 per cent. are sterile, but this figure rises to 60 per cent. when they are closely confined. Darwin calls attention to the fact that mares rarely get in foal just after being taken from the stable and turned to pasture.

In what way consanguinity acts in causing sterility is not known, but it is a common cause in both the lower animals and man. Interbreeding of stock will cause the most improved breeds to degenerate in a very short time, and in families we see the same result, the progeny becoming sterile, deformed or mentally deficient. Mitchell points out the fact that this can be partly averted by good food and hygienic surroundings.

Galton, who has studied the question of hereditity in all of its bearings, more thoroughly than any one else, finds that it is a potent factor in producing sterility. In England, where only-child sterility is as frequent as one in every thirteen marriages, Susell finds heredity one of its chief causes. The absence of menstruation has been given by some authors as a cause of sterility, but this cannot be, for it only indicates a condition of the ovaries unfavorable for ovulation, and should be considered as a symptom. When it exists up to the 20th year, it is usually a sign of non-development or atrophy of some of the internal organs of generation. From the forty-sixth to the fiftieth year it usually becomes permanently established and indicates the presence of senile sterility. The menses may also be arrested by catching cold, by fright, or by any great physical or mental excitement, and generally indicates a condition unfavorable for conception.

2. *Non-union*.—Non union of healthy ova and spermatozoa may be caused by: *a* absence, stenosis, atresia or dilatation of any part of the course traversed by the human germs; *b* by diseased conditions of the passages which tend to impair the vitality of either ova or spermatozoa; *c* by artificial means employed to prevent conception; *d* by all influences tending to hasten, prevent or retard orgasm.

Male.—(a.) The possible existence of the ovaries, with the absence or imperfect development of one or all of the remaining internal organs of generation—those developed from the Wolffian bodies and the conduits of Müller—is well known, and it is but reasonable to suppose that the corresponding portions of the male genital tract—the ducts from the testes to the urethra—can also be absent or undeveloped while the testes are present. Such a condition must prevent the entrance of semen into the urethra.

Dunley found that in old age an obliteration of the ducts took place, probably before the testes ceased to generate spermatozoa. Pressure from tumors of the cord may also cause occlusion of the ducts. Epispadias, hypospadias and urethral fistula, unless situated near the glans penis, will allow the escape of the semen before it enters the vagina, and in those cases where it is deposited in the vagina it fails to be ejaculated against the cervix.

Stricture of the urethra is a very common cause of sterility. When narrow and situated in the anterior portion of the urethra, it obstructs the canal during erection so as to dam up the semen till the organ becomes flaccid, when it gradually oozes out. Should the stricture be situated far back, a regurgitation of the fluid may take place into the bladder, and be passed only as the urine is voided. When a slight stricture is present, impregnation may be affected by a change in the normal spiral direction of the urethra. This, as a rule, twists from right to left, as can be seen when passing urine from a healthy urethra, and it can also be demonstrated by passing a large olivary bougie well back into the canal and withdrawing it by a small thread attached to its end. In connection with this it is interesting to note what Courty says, in speaking of the "arbor vite" of the cervical canal. "The posterior tree," says he, "deviates to the left in proportion as it approaches the superior orifice. The anterior tree is, on the contrary, directed towards the right." It will be observed, then, that when the meatus urinarius is applied to the external os uteri, the spiral is continuous to the cavity of the uterus. Phimosis and stenosis of the meatus urinarius have the same effect as stricture, and a too large meatus acts in the same way as hypospadias.

(b.) Levy has shown that catarrhal secretions, when containing many pus corpuscles and much epithelial detritus, destroy the vitality of the spermatozoa in a very short time, but it is not probable that urethritis, simple or specific, will directly cause sterility in many cases, as it is such a short time in contact with the spermatic fluid. I recall a case in my own practice in which impregnation and gonorrhoeal infection, in all probability, took place from the same individual at the same time.

(c.) Little need be said about the artificial means

used by the male to prevent conception. The practice of "withdrawing" as orgasm approaches and the use of the condom are only too well known to all classes, both married and single.

In some parts of France and Syria, the prostitutes adopt a practice not generally known in America. It consists in tightly compressing the male urethra in front of the prostate, as orgasm approaches, so as to cause a regurgitation of semen into the bladder.

(d.) Many men of excitable dispositions, when first beginning to gratify the sexual appetite, are unable to control themselves and have a premature emission, sometimes even before entrance into the vagina has been gained. One individual under my care, who has since married and begat children, would have a seminal discharge as soon as his limbs came in contact with those of a female, even when sitting at meals.

Different neuroses of the genital tract may retard or prevent orgasm, and in one case which came to my notice I had reason to believe that spasmodic stricture of the urethra caused seminal regurgitation into the bladder. These neuroses are found in persons who have been addicted to excessive venery or to masturbation, and in those who have suffered from frequent or long-continued nocturnal emissions. In all debilitated individuals, from any cause whatever, or in those suffering from affections of the nervous system, the reflex centres governing the ejaculatory act may lose their excitability, so that, though erection takes place, there will be no discharge of semen. It is a not uncommon complaint of sterile women that they feel no discharge from the man during coitus. Non-erection prevents orgasm, and this may be caused by physical or mental affections. In some cases a too rapid flow of blood through the dorsal veins of the penis may bring this about.

Female.—(a.) Congenital defects, preventing the union of the ova and spermatozoa, may be found in any part of the female genital tract. Kisch calls attention to an abnormal thickness of the tunica albuginea as an obstacle to the escape of the ova, and Schenk has seen the cellular covering of the zona pellucida, as it escapes from the Graafian follicle, act as an obstacle to the entrance of the spermatozoa, in rabbits.

Should the outer portions of the conduits of Müller, one or both, fail to develop, or their blind extremities neglect to open, there may be an entire absence or a rudimentary development of either or both of the tubes, or it may result in a closed termination where the fimbriated extremities should be. If an imperfect fusion of the lower portion of the conduits of Müller take place, it will result in some abnormal shape in the body of the uterus, but this does not prevent conception, nor does the imperfect condition arising from lack of development of one of the conduits of Müller.

The septum dividing the conduits may persist in all or any part of its course, and cause the formation of a double uterus or double vaginae, but this is an impediment to impregnation only when it prevents copulation—conception being possible in either or both sides of the uterus. Should the conduits fail to develop or should they be arrested in their growth, the result will be an absence or malformation of both, either, or any part of the uterus or vagina, and any of these conditions may exist in females who are apparently well developed.

Examples of entire absence of the uterus are quite numerous, its diagnosis being easily made, on the living individual, by introducing the finger of one hand into the rectum and a probe, catheter, or finger of the other hand into the bladder.

Total or partial absence of the vagina may exist when the uterus is present or when it is absent, and this abnormal condition can be diagnosed in the same way as the abnormal conditions of the uterus. Should only the lower portion of the vagina be absent, it does not necessarily cause sterility, for the genital canal may open into the urinary or intestinal tracts, and there are cases of this kind on record where impregnation took place through the anus or the urethra. If, during fetal development, the free edges of the hymen unite so as to entirely close the opening to the vagina, sterility must result. In all other anomalies of the hymen impregnation is possible, though the penis may not gain access to the vagina, and many cases of impregnation without penetration have been recorded, the spermatozoa having found their way through the opening into the cervix uteri. Congenital malformations of the vulva are also found occasionally, in which coitus is impossible. It may be abnormally small, or there may be adhesion of either the labiæ majoræ or the nymphæ. This union may be simply between the epithelial surfaces and easily overcome by traction, or it may be firm and require operative interference.

A small vagina, as a rule, is not a serious drawback to conception, and Kisch calls attention to the fact that small women with large husbands—presumably where the fit is tight—are more prolific than where the two are of the same size, or the woman is larger than the man. The above statement is borne out by my own observations. Congenital atresia of the cervical canal may exist in any part or all of its course. If situated only at the external os, as is most frequently the case, it usually consists of a continuation of the mucous membrane across that opening, and is easily remedied, but when more extensive it is difficult to treat. It usually attracts attention about puberty by the formation of a hematometra. Acquired atresia of the cervical canal is quite a common occurrence in women after they have passed the menopause, but here it is usually at the in-

ternal os, and is due to adhesion following degenerative changes.

Stenosis of the cervical canal may occur at either the external or internal os, and can be determined by the failure, in any uterus of normal position, to pass a good-sized uterine sound with ease. Olshausen calls attention to the fact that in women who bear their first child long after marriage a second birth follows close on the first, and he accounts for this by the stenosed os becoming larger after the child has been born. A lady of my acquaintance was barren for six years after her marriage, since which time she has given birth six times in nine years. Stenosis of the cervix is a common cause of sterility not only in man but also in the lower animals. The Arabs use the hand and various hard instruments for dilating the cervical canal in mares that are unfruitful, and the Tyrolese incise the cervix of barren cows, in both cases, it is said, with successful results. The intra-vaginal portion of the cervix may be abnormally short or entirely absent, and in either case may cause sterility by preventing the application of the glans penis to the cervix uteri. Hypertrophy of the vaginal portion, if general, results in an elongation of the cervix, which is so great in some cases as to prevent coitus. This great length is exceedingly rare, but moderate elongation is quite common, and causes the cervix to be displaced as the seminal discharge takes place. If the hypertrophy is confined to one side it results in flexion, so that the os is tilted towards the vaginal wall during coitus. The conical and the nozzle-shaped cervixes indicate an abnormal condition of the muscular structures, and probably prevent an active participation of that part of the uterus in the act of coition.

Where the cervix is torn or everted, sterility may be caused by the granulations closing the canal so as to prevent the passage of the spermatozoa, by the cervix allowing the escape of the semen after it has entered the canal, or by a catarrhal condition of the lining membrane causing a change in the normal secretion which is unfavorable to the life of the spermatozoa. A lacerated perineum also favors the escape of the semen and promotes secondary changes in the internal genital organs unfavorable for reproduction.

All uterine displacements, whether from a relaxed condition of the ligaments, from increased weight or external pressure, or from the contraction of inflammatory deposits, tend to prevent the entrance of semen to the ova.

In inversion of the uterus conception is necessarily impossible, and next to this version are most certain to produce sterility, for not only is the cervix tilted out of the way but the os is covered by the vaginal wall as with a lid. In flexions the obstruction is in the canal at the

point of greatest convexity, but this is somewhat overcome by the congestion and erection taking place during coitus.

In prolapse, unless complete, there is nothing to prevent conception except the debilitated condition of the uterus and vagina, for the penis naturally pushes the organ back towards its normal position as it comes in contact with the cervix.

Hervey relates an interesting case of procidentia uteri where coitus took place through the dilated cervical canal and was followed by conception.

As the uterus becomes displaced it draws upon and displaces the tubes to a certain extent, and in this way the entrance of semen into their uterine extremities or of the ova into their fimbriated extremities may be retarded.

Displacements may also prevent conception by producing congestion and thickening of the lining membrane of both the uterus and the tubes so as to occlude these channels.

Contracted pelvis may also prevent the union of ova and spermatozoa by hindering coitus, and Hofmann has recorded an example of this kind where connection was impossible.

Atresia or stenosis of any part of the genital tract may be brought about by inflammatory trouble. All pelvic inflammations—salpingitis, ovaritis, peri-metritis, para-metritis, etc., properly included by Dr. Georges Apostoli under the term “salpingo-ovaritis”—originate almost always in the uterine mucous membrane and spread from there, through the tubes, to the surrounding organs where inflammatory products are thrown out, the contraction of which results in a dislocation of the uterus, of the ovaries, or of the tubes, or in a closure of the lumen of the tubes. The lining membrane of the tubes also becomes thickened and when closure takes place in two or more places so as to prevent the escape of the secretions into the uterine or peritoneal cavities there results a hæmato-, hydro-, or pyosalpinx.

Inflammation of the fimbriated extremities is quite common, and a dropsical condition may be found which causes an obstruction to the entrance of the ova into the tubes. In a case of laparotomy where I removed the right ovary the end of the tube was found inflamed, adherent to the ovary and closed, but it was healthy in all the rest of its course.

Tubercular disease may attack the tube, but the most common cause of salpingitis is an endometritis of gonorrhœal origin.

Acquired stenosis or atresia of the cervix may follow injuries during labor, or it may be due to syphilitic ulceration. In follicular endo-cervicitis the canal may be entirely closed by the enlarged follicles, or ulceration and contraction may take place, thus causing atresia or stenosis and preventing the entrance of the semen.

The application of the sharp curette or of too

strong medicinal applications may bring about the same results through cicatrization. Vaginal stenosis or atresia may be due to injuries during delivery or to syphilitic ulceration. Diphtheria may also cause sloughing and subsequent contraction. Simpson has seen simple vaginitis in children result in stenosis, due to an epithelial denudation with subsequent adhesion of the vaginal walls.

Vaginismus is a hyperæsthetic condition of the genitals, usually in virgins, causing a spasmodic contraction of the muscles of the perineum and vagina. It may be due to the small size of the vagina, to ulcers and fissures, to irritability of the hymen, and to organic disease of the uterus. Winckel reports cases in which subperitoneal fibroids seem to have been the cause of it, and Martin gives cold as one of the causes. In many cases self-abuse in childhood seems to have produced a congested and hyperæsthetic condition of the parts. This was the only cause that I could find in a married lady of nineteen, who had been married for nine months without ever having had connection. The hymen was elastic and normal in appearance, but when any attempt was made to introduce the finger into the vagina, intense pain was experienced and a spastic closure of the sphincter vaginae would occur.

E. Davis reported an interesting case where he was sent for by a gentleman to separate his coachman and maid, and this could only be accomplished after chloroform had been administered to the woman. The liberated organ showed that there had been a constriction at the sphincter and one higher up in the vagina.

Hypertrophy or new growths of any of the external genitals may be an obstacle to coitus and thereby a cause of sterility.

The clitoris may be so developed as to prevent the access of the male to the female. Hyrtl states that in certain of the African tribes the size of the clitoris is so great that it is fastened to the perineum by rings so as to act as a protection to virginity. It was most likely on account of its size that circumcision was formerly practiced in certain parts of Egypt, and is now in parts of the Turkish dominions. Elephantiasis of the vulva is sometimes a cause of sterility, and hypertrophy of the nymphæ is said to be a frequent cause among the Hottentots, Bushmen and Abyssinians. A large accumulation of fat on the pubes and around the vulva is a not infrequent cause of sterility in persons of somewhat advanced age. Benign and malignant growths of the perineum will prevent the introduction of the penis into the vagina. In a girl of 16 years, from whom I removed a large angioma of the right labia majora, coitus would have been almost impossible.

The vagina may also be so obstructed as to prevent the union of the ova and spermatozoa. This may be caused by cysts, fibrous tumors,

polypi, and malignant tumors of the vagina; by pressure from ovarian or rectal tumors; or by cystocele, rectocele, or enterocele. Kisch reports a case in which a mass of hardened feces in the rectum prevented coitus, and Schulze had a case in which the perineum of a 14 year old girl was developed to such an extent that the urine was passed with difficulty.

Tumors of the uterus may prevent conception by occluding either the os uteri or the openings of the tubes; they may also cause displacement of the ovaries and tubes, and when very large they may draw the uterus up so as to be out of reach of the glans penis. Indirectly uterine tumors may cause congestion or inflammation of the genital tract producing a condition unfavorable to the passage of the spermatozoa.

Hennig has recorded an interesting case in which hydrocele seems to have been the cause of sterility. Ovarian tumors may prevent the entrance of the spermatozoa either by causing compression or by drawing up the uterus, as in the case of large uterine tumors, and the same is true of tumors of the broad ligaments.

(6.) The normal vaginal secretion is slightly acid, and as stated before, unfavorable to the life of the spermatozoa, while that of the cervical canal is alkaline and will preserve their vitality for several days. Should, however, an inflammation of any part of the genital tract be set up, the spermatozoa, as has been shown by Lott, lose their vitality and die in a short time. This may be caused by vaginitis, endocervicitis, endometritis, or salpingitis. It is probable that the ova are also injured by coming in contact with diseased secretions, but on this point our knowledge is not definite.

There are many causes which may produce inflammation of the genital tract, but the most frequent of all is gonorrhœa. Nöggerath thinks that "latent gonorrhœa" is the cause in 90 per cent. of all cases of sterility. This figure seems too high, but it may be correct for the inhabitants of large cities.

Diseased conditions of the genital tract produce sterility more frequently by offering a mechanical obstruction to the entrance of the sperm, or by rendering the endometrium unfit for the implantation of the ova than by destroying the vitality of the germs.

Urinary and fecal fistula of the genital tract prevent conception not only because of the sense of disgust connected with them, but also by producing a diseased condition of the mucous membrane.

(c.) Among the artificial means used by women to prevent conception may be mentioned sponges and tampons of cotton introduced into the vagina against the cervix. Small rubber caps are also used by placing in the vagina so as to fit as a cap over the cervix uteri and thus prevent

the entrance of semen into the cervical canal. Other means are used to destroy the vitality of the spermatozoa. Among these may be mentioned injections of hot and cold water, and solutions of vinegar, alum, boracic acid and other medicinal substances. These methods are not as sure and much more injurious than the former. Abstinence from coitus for fourteen days after the last menstrual period and for three or four days before the appearance of the next flow is also a pretty safe practice, there being no ovum in the tract at that time.

The sexual desire in the male is much stronger than it is in the female, and in some females it is entirely absent. I have questioned many women on the subject and have frequently been told that it was months, and in some cases years after marriage before they could look on sexual intercourse with any feeling but disgust. This has been told me so often that I am inclined to think that the desire among the more highly educated women is educated and not natural. This also accounts for the fact that the first birth among the better classes is postponed longer than among the laboring classes. Most likely this is due to the development of the cerebrum at the expense of the cerebellum, and in time it is possible that the better class of Americans may become extinct, as have the cliff-dwellers, in whom, judging from their crania, the "organ of philoprogenitiveness" was poorly developed. Many women claim to be able to tell the exact time at which impregnation occurs, and there seems to be good grounds for accepting these statements as true. This is probably due to the perfect orgasm taking place in both parties at the same time. I have ascertained from many prostitutes that though they go through all the motions, when having intercourse, they allow orgasm to take place only when they are with their lovers. To this cause they ascribe the fact of not becoming pregnant and also of retaining their health for a long time. A married woman, whose husband is now suffering from syphiloderma, informs me that she has escaped contracting the disease by not allowing her passions to be aroused, and by bearing down and forcing out the seminal fluid after the act has been accomplished.

We see then that orgasm is more or less under the will-power, so that it can be hastened, retarded or kept in abeyance. It is also affected by all influences which debilitate the body or the nervous system. All agents then which tend to prevent complete and simultaneous orgasm in the two individuals are causes of sterility.

3. *Nonimplantation.*—Nonimplantation of the impregnated ovum in a healthy uterus may be due to disease of the tubes or of the uterus. After the ovum has become impregnated, most likely in the outer part of the tubes, it is carried by the current in the tubes, which is caused by the mo-

tion of the ciliated epithelium and which is probably assisted by a peristaltic action of the tubes, to the uterus. The uterus is also lined with ciliated epithelium whose motion is towards the tubes. This motion probably assists the entrance of the spermatozoa into the tubes and also acts as an impediment to the downward passage of the ovum. We have seen before that ovulation and menstruation are closely connected, so that by the time the ovum has reached the uterine cavity the endometrium has become swollen and its outer layer, at least, has been thrown off as detritus so as to offer a suitable nidus for the ovum. Here, if all is favorable, the impregnated ovum becomes attached and remains, undergoing development, till normal delivery takes place.

The frequent arrest of the ova in the tubes is shown by the number of cases of ectopic gestation. Mr. Tait claims that all cases of extra-uterine pregnancy are primarily of tubal origin. He admits the possibility of ovarian pregnancy, but denies that it is possible to have a case of primary abdominal pregnancy, and his assertions are borne out by recent investigations.

The arrest of the ovum in the tube may be caused by peritoneal or cellular inflammation, in which a constriction is brought about by the contraction of the inflammatory products; by pressure from tumors and new growths; by catarrh and swelling of the lining membrane, which may also affect the ciliary motion of the epithelial lining or the peristaltic motion of the tubes, and by pouches or dilatations in the tubes where the action of the current is lost.

The uterus may be sufficiently developed to receive the ovum and yet be unsuitable as a seat for future development. An arrest of growth may take place in fetal life, before the uterus and vagina have become differentiated, giving the "uterus fetalis," or its growth may be arrested in infancy while the cervix is very long and the body undeveloped, which results in "uterus infantilis," which, according to Biegel, is as frequent in cases of sterility as 4:155. Winckel has shown that fetal inflammation is a frequent cause for non-development of the uterus. Atrophy of the uterus may also be acquired, as in the condition known as "primary atrophy," which occurs in girls before the period of puberty, when they suffer from wasting constitutional diseases, from anemia or from chlorosis. In weak mothers, who have suffered from puerperal complications, it is not uncommon to find the menses suppressed and the uterine walls in a thin and flaccid condition. This is known as "puerperal atrophy" of the uterus. A condition of the uterus which is unfavorable for implantation or development of the ovum may be brought about by inflammation of the peritoneum and cellular tissue surrounding the uterus; by inflammation of the uterine parenchyma, or by inflammation of the endometrium.

Peri- and para-uterine inflammations may spread to the uterine tissue itself, but most frequently they contract and produce displacements of the uterus or bind it down so that when the ovum enlarges abortion follows. They may also prevent the return of the venous blood from the parenchyma of the uterus, which results in hyperplasia, with a subsequent catarrh of the endometrium. Hyperplasia may also be produced by disturbances of the circulation due to valvular disease of the heart, but it most frequently follows the first birth and is caused by subinvolution.

The constant excitement due to excessive venery results in hyperplasia, and we find flexions producing the same results, but by arresting the return of the venous blood.

In all cases of hyperplasia the endometrium is found congested and the secretion from its glands, and the glands of the cervix, much more profuse and watery than when in a normal condition. It is probably in this way that hyperplasia acts, for in many cases where the endometrium is not too much diseased pregnancy occurs in spite of the thickened uterine walls. Hyperplasia may run into chronic metritis where true inflammatory products are thrown out, and this will prevent the development of the ovum even though it become attached.

As stated above, the inflammations around or within the uterus may extend to the muscular tissue proper, in which condition we find hemorrhages from the endometrium quite common, and in this way the ovum, after having reached the uterine cavity, may be washed out. The cavity of the uterus also becomes larger than normal so that there is less chance for the arrest of the ovum, the nutrition of the endometrium is more or less disturbed so that implantation of the ovum is not likely to take place, and the irritability of the nerve supply is favorable to uterine contraction, which frequently results in the expulsion of the ovum.

Inflammation of the endometrium is the most frequent, directly or indirectly, of all causes in producing sterility. We have seen how it may produce changes which prevent the entrance of or are injurious to the vitality of the spermatozoa.

We have also seen how most para- or peri-uterine inflammations start from the endometrium, and either affect the production of the ova or prevent their union with the spermatozoa. It now remains to consider how inflammations of the endometrium may prevent the implantation of or development of the impregnated ovum. In endometritis there is a production of many small round cells which are deposited between the glands, so that compression of the glands takes place and results in atrophy, not only of the glands, but also of the mucous membranes. With this the secretion becomes thin and watery and

its reaction is altered, while the ciliated epithelium is thrown off and replaced by cylindrical and polyhedral epithelium. This gives a smooth and slick condition to the endometrium so that the arrest of the ovum in the uterine cavity is very difficult, or, should it be arrested and become implanted, the atrophied condition of the mucous membrane with the alterations in the subjacent tissues will favor its early expulsion.

All intra uterine growths, whether submucous fibroids, polypi, malignant or other tumors, prevent implantation or favor early abortion by altering the condition of the mucous membrane, or by offering a mechanical resistance to the development of the ovum.

Growth in the muscular tissue also alter the condition of the mucous membrane, but they act chiefly by preventing the uniform enlargement of the uterus as the ovum develops. The subserous growths may produce a condition closely resembling vaginismus and, if impregnation occur, the excitable condition of the nerves may cause early abortion. Intra-abdominal tumors may, if large, be an obstacle to the development of the ovum by directly compressing the uterus, as is sometimes seen in cases of multilocular ovarian cysts.

Cancerous tumors act by infiltrating the tissue of the uterus as well as by preventing copulation through the sense of disgust connected therewith. Should laceration of the cervix extend nearly up to the internal os it causes infiltration of the uterine tissue, which results in a loss of the relation between the ovum and uterus as development progresses, of which abortion is the consequence. Membranous dysmenorrhœa is in some cases a cause for the discharge of the ovum, but not in all cases, for many examples of child-bearing have been reported in women who were suffering from that trouble. Another cause for non-implantation of the ovum, which is probably more frequent than is generally supposed, is the application of the sharp curette or strong medicinal substances to the endometrium by unskilful hands. Their value, in suitable cases, when carefully applied, can not be over-estimated, but if the mucous membrane be destroyed in its entire thickness it must be replaced by cicatricial tissue unsuitable for the implantation of or nourishment of the ovum.

To enter into the subject of abortion would be rather foreign to the present subject, and it would require too much space for the present paper. Suffice to say that where habitual abortions occur, if neither the father nor the mother show any signs of syphilis, attention should at once be directed to the uterus. I have under my care now a lady who has aborted five times, and it was only in her last accident, the first in which I attended her, that a large uterine polypus was discovered. The trouble was supposed to be due to "habit."

(To be concluded.)

IN WHAT CLASS OF WOUNDS SHALL WE USE DRAINAGE? AND THE PRESENT POSITION OF ANTISEPTIC SURGERY.

BY HENRY O. MARCY, A. M., M. D., LL. D.

Dr. Marcy considered at length the subject viewed from the standpoint of the recent discussion at the International Medical Congress held in Berlin. He reviewed in detail the observations of Metschnikoff upon the power of the leucocytes to surround and destroy, to digest (so to speak), the bacteria when circumstances are favorable. It seemed to the writer quite too early to draw general deductions from these premises and declare that here the entire solution of the problem is found. There is every reason, however, to believe that this is an important discovery of a power which the organism brings to rescue it under favorable conditions from impending danger. The practical deduction of the lesson is that we seek to place the wound in such a condition that the phagocytes of Metschnikoff may be made the active allies of the surgeon. All this helps also, in a measure, to explain the successes which surgeons have obtained by means which seemed directly opposite in their methods of wound treatment.

Dr. Marcy carefully reviewed our present knowledge of the histological changes which go on in an aseptic wound, and showed that the so-called phagocytes had long been known to science as the leucocytes which, under favorable circumstances, develop into germinating tissue-cells with the newly formed capillary vessels, etc. A somewhat similar series of observations of equal interest and importance are seen to ensue about the ligature of an artery in continuity when the surrounding parts are maintained in an aseptic or healthy condition. Here repair takes place by the host of little workers leading up their forces in different directions. The blood-clots in the extremity of the occluded vessel undergo changes not unlike those already referred to in other locations, while the leucocytes speedily surround and shut in the material used as a ligature, forming a capsule. At an early period this may be lifted away from the thread, more or less distinctly as a layer, and little or no change has taken place in the constricting material, although this may differ very widely in character. Even when applied to the vessels of very young animals, after a considerable period, the silk ligature is comparatively unchanged. Often at the end of three or four weeks it may be found intact, although firmly shut in by a sheath of new connective-tissue cells.

When the tissues are held at rest, the same general condition may be observed, if silk-worm gut or silver wire has been used. After a period

of some weeks, the silk ligature may have completely disappeared, and the changes which have led up to this are traced in an invasion of leucocytes between the strands and fibres of the silk, slowly separating them and causing their disintegration. If these conditions are interfered with in a mechanical way, this process seems to be held in abeyance.

The cell changes which should go on in the development of connective tissue fail, and then the little army of workmen invade the surrounding tissues, and the processes, earlier called proliferating, ensue, and the constricting material is thrown off as a foreign body. When an aseptic animal ligature has been used, catgut or tendon, and the parts about maintained in a healthy state, the ligature material becomes invaded by leucocytes, which utilize it for their own development, causing it, little by little, to disappear. So marked is this process that an aseptic animal suture, introduced into various parts of a healthy young animal, may for a considerable period be traced by a line of newly-developed connective tissue, although not a single vestige of the original material remains. These processes have for a long time been recognized in a general way and accepted, and yet we are all familiar, almost equally so, with the reverse of the picture, where any considerable colony of micrococci develop in the line of a wound.

Here this process may be completely local; that is to say, the leucocytes surround and shut in the invading army with a wall of living granulation cells until, little by little, it is forced to surrender and a localised abscess is the sum total of damage. The most of us, however, who were surgeons of an earlier day recall the too common and, I am sorry to admit, even at present, not rare experience in the every-day work of many—the foul suppurating wounds and general systemic poisoning. In such wounds the feeble barriers of leucocytes, thrown up against an invading army, fail to protect the organization, and the much-dreaded “blood poisoning” supervenes.

If it may be accepted, in a general way, that the above observations are correct, let us use them as basic and fundamental from which to draw further conclusions. If we find in the so-called phagocytes of Metschnikoff the familiar leucocytes above mentioned, we certainly have, in a very considerable measure, an explanation of the vital resisting power of the individual organism. If, under favorable circumstance, these cannibalistic little workmen not alone surround, but actually eat up their enemies, we have the best of reasons for understanding why the comparatively few germs in the atmosphere of a healthy locality are far less dangerous to wounds than was earlier supposed. Again, too, we see that in the so-called surgically clean wound, that is a wound where great care is taken to exclude foreign ma-

terial, where blood-clots are removed, and the comparatively uninjured clean-cut surfaces are closely approximated—the reparative processes go on steadily, and rapid recovery supervenes, although in a strict scientific sense the wound is not aseptic.

In wounds where the surrounding tissue is devitalized these favorable conditions are not maintained, and here the germination of bacteria goes on much as seen in laboratory culture experiments.

Dr. Marcy then reviewed at length the important contribution of Sir Joseph Lister, delivered before the Medical Congress in Berlin, and Mr. Tait's reply to the same holding, as usual, opposite views, he declaring that the whole basis of antiseptic surgery is, “an absolute and ludicrous logical error.” Dr. Marcy closed his address with the conclusion, that the unbiased student must observe in the recent progress in wound treatment a fundamental truth based upon the repeated observation of abundant facts. This consists of three factors: 1. The condition of the patient, the so-called vital resistant power; 2. The bacterial infection, the seeding of the field; 3. The condition of the soil, the pabulum necessary for the growth of the direful harvest. Upon this tripod at present rests the scientific basis of wound treatment. There are many workers equally earnest, equally thoughtful. It is better they should make their observations as independent original investigators. Much profit comes from the results of such heroic workers, as Mr. Tait, Dr. Bantock, and many others we could mention. The recent teachings of those who advocate the so called dry treatment of wounds convey another side view of the great fundamental truth of much value. Here primary union is prompt and there is little effusion which seems to require drainage. It will be noted that Sir Joseph Lister looks forward to the possible abandonment of drainage, which he has during the last three years greatly lessened. On the contrary, Mr. Tait, as may be inferred from his writings, elevates drainage to a most important factor of wound treatment, and at the late International Medical Congress, both he and Dr. Bantock predicted a greatly extended use of the drainage-tube. They disregard the bacterial infection, but insist upon the withdrawal of all material which could aid in its possible development.

The ideal of wound treatment is surely to restore the condition of the parts to as nearly their primal state as possible. If this can be assuredly aseptic, then there is no bacterium to remove; if surgically clean, with accurate coaptation of the sundered parts, then there is no material which needs removal, nothing to drain. If, as we have seen, the leucocytes go promptly to work under such favorable conditions, the first series of the repair processes takes place, which ends in a prompt

and speedy restoration. This should be effected under a dressing which will permit of the introduction of no foreign factorage. To this end Lister has unweariedly labored, for nearly a quarter of a century. The various antiseptic dressings, now so generally employed, have a value in wounds necessarily drained, which must be considered open to a possible infection, but in a wound that is closed without drainage they are unnecessary, expensive, and cumbersome. Lister's ideal protective varnish is found in the closure of the wound with iodoform collodion.

My last five years of experience in the treatment of aseptic wounds of every variety, closed in layers with buried tendon sutures and treated in no other way than by a protective layer of collodion, is cited in ample proof. Even in the major amputations, such wounds go on to a speedy repair without pain or oedema of the surrounding parts. Call the various methods adopted to secure the end obtained by whatever name you will, the great fundamental principles of antiseptic surgery, as enunciated by Sir Joseph Lister many years ago, rest upon a sure foundation, and the results in modern wound treatment are the marvel of our age.

From this brief review of well-known facts, it is obvious that the real object of drainage is not so much the removal of the serum, blood, and devitalized tissues, as it is to remove any possible bacterial infection which may have invaded the wound; for it is quite impossible to divide and rejoin tissues without the effusion of blood and serum, and in a greater or less degree devitalizing the adjacent structures. Since these are very important factors, it is of the first consideration on the part of the surgeon, that he minimize as much as possible these conditions, for the reason that they render it very probable that the introduction of bacterial *seed* into such a *soil* will be followed by direful results.

Is the present state of operative procedure sufficiently accurate to warrant the assurance that such complications are not to supervene? This is the question which must first be satisfactorily answered before we are in a position to determine at all positively when we are to use, if always, or not at all, the drainage-tube, in the hope thereby to remove the fermenting material, so dangerous if allowed to remain.

It is certainly clear that the experience of the last twenty years has been leading to the solution of this problem, until now it seems demonstrated beyond a doubt, that an *aseptic* wound may be made in *aseptic* tissues, and maintained aseptic until restoration is complete. If this is true, the *modus operandi* of modern wound treatment must be mastered as the ritual service of a higher religion, before the surgeon is competent to enter upon the serious responsibility of his office. If aseptic conditions are maintained, then we may

safely conclude that the drainage of the wound will not be necessary, and if unnecessary, certainly undesirable. At the best the drainage tube is a foreign body, and its presence in the wound prevents primary union of that portion of the tissues which enclose it. It keeps the wound, to a certain extent, an open one, and as such makes secondary infection so probable that the most careful antiseptic dressings are advised to absorb and disinfect secretions and prevent atmospheric contamination. In an aseptic wound, after the removal of the tube, the final closure of the tract is comparatively slow, and by granulation. These are well-recognized objections, and efforts have been made to overcome them by many ingenious designs.

If drainage is to be discontinued in aseptic wounds, it must be accepted that the greatest care should be exercised in leaving as little devitalized tissue as possible, and in evenly coaptating the divided parts. The wound should be clean and dry; the different layers of the tissues should be joined with as little injury as possible, and the external wound should be protected from infection. Irrigation should be employed with a minimum of sponging, and joining of the tissues by light, running buried animal sutures, preferably tendon. The skin is evenly coaptated by a similar suture, taken from within outward through the deeper layer only. Then the wound is sealed with a germ-proof layer of iodoform collodion reinforced by a few fibers of cotton. Such wounds go on rapidly to repair without oedema of the tissues, pain, or tenderness.

"Are all aseptic wounds to be thus treated? I unhesitatingly say yes, even to the major amputations; abdominal operations included."

As a matter of fact, I find in my last forty abdominal sections I have not once used drainage, and have noted no reason to regret not employing it.

The *seed* and the *soil*, and the varying conditions of each, must ever be kept in consideration. When in doubt of infection in a wound, especially when its character will be likely to be attended with an abundant albuminoid secretion, drain; but let the surgeon ever remember that the highest theoretic condition of wounds is their restoration, as nearly as possible, to the normal relation of the tissues, and their retention at rest in an aseptic condition. This, in a great majority of wounds, renders drainage not only unnecessary, but when applied, it will be a positive detriment and a source of danger. I am assured that the better knowledge of the conditions of wounds will restrict the use of the drainage-tube to septic wounds, and that operative wounds in aseptic tissues will be aseptically maintained by primary closure without drainage.

(For discussion see Society Proceedings.)

DEATH DURING CHLOROFORM ADMINISTRATION.

Read before the Medical-Legal Society of Chicago, Dec. 6, 1890.

BY C. T. PARKES, M.D.,

PROFESSOR OF SURGERY RUSH MEDICAL COLLEGE, ATTENDING SURGEON PRESBYTERIAN HOSPITAL, ETC., CHICAGO.

The case which I desire to report to-night is rather a notorious one, and I have concluded to report it at the request of the President, without preparation, because it is of great interest to the profession, and because I am quite sure there is no one who will better remember the circumstances attending the case or who will be less likely to forget them. It is a case of death which resulted in a child under the influence of chloroform during the month of November last. These cases are always doubly unfortunate. They are unfortunate in the first place, and beyond all other reasons, on account of the death of the individual, and the terrible news which is so suddenly brought to the bereaved friends. They are unfortunate because they remind the profession of the fact, which cannot be disproved, that physicians have not found an absolutely safe anæsthetic. All anæsthetics are dangerous, and all of them occasionally cause death, and the most astounding part about it to outside individuals is, that doctors cannot tell why the patients die under these circumstances. These cases of death under anæsthetics are always unexpected, and in the vast majority of cases unavoidable.

This patient was a bright, perfectly healthy little girl, about 11 years of age. She had on her face a large mole covering the greater portion of the surface of the cheek, measuring more than two and one-half inches in one direction and over one inch in another. It was dark in color and had on it a large growth of coarse hair. It was a source of very great annoyance to the child, increasing her timidity, and of great trouble to the friends. I, and other physicians who saw the case, recommended its removal because we had had experience in such matters, had done such operations safely, and because it could not be removed in any other way than by surgical operation. There was nothing in the appearance of the child upon examination that would counterindicate the use of an anæsthetic in any way, and chloroform was chosen; because, personally, I do not believe there is a noticeable amount of difference between the two anæsthetics, chloroform and ether. The difference which seems to exist I believe is based upon the fact, that a larger number of physicians use chloroform than use ether. And although the number of deaths recorded as following the use of chloroform are greater than from the use of ether, it is dependant upon the fact that chloroform is used oftener than ether. But the fact still remains that all anæsthetics and all combinations of them have been

followed by unexpected death in individuals who were healthy as well as in those who were diseased, and the post-mortem examinations made after death have in no case shown satisfactorily the cause of death, so we do not understand absolutely why they die.

In this case the anæsthetic was commenced in the room which the parents of the child occupied, and was given by an interne, Dr. Gill, of the Presbyterian Hospital. At first the child exhibited no more excitement and no more opposition to taking the chloroform than do other patients, and not nearly as much as many. It is the constant experience of physicians that they are compelled often to use physical force for some time before the patient is anæsthetized; that was not so in this case. I was a little anxious about the case and was ready to do the operation, but the patient did not appear, so I sent a second interne, Dr. Jay, to see what the trouble was. He did not return for some time and I sent the chief assistant, Dr. Ochsner, and in a few minutes the child was brought into the room quietly asleep. The anæsthetic was then given into the hands of the oldest interne, Dr. Albright, and he administered it carefully during the operation. The operation required about twenty-five minutes; it was about the face, and my hands, which are not very small, were over the child's face all the time and consequently the anæsthetic was not used steadily, very little chloroform was given to the child. The instrument used for giving the anæsthetic was Esmarch's inhaler, a wire frame covered with flannel, with which it is impossible to absolutely prevent the entrance of air. The child made no demonstration of any kind that would attract attention. The operation was practically completed; the pigmented naevus was removed and pieces of skin taken from the thigh for transplantation, to cover the defects and diminish the amount of scar, were being put in position; when, without any warning, without the administration of any chloroform for at least five minutes, the child was seized with general convulsions; she ceased to breathe, her heart ceased to beat, she gave a few gasps and was dead. Every effort was made for an hour and a half to restore circulation and respiration, by artificial respiration, injection of ether and whisky and nitrite of amyl, and the use of electricity, but all efforts failed.

The case is interesting to all medical men, and to all lay people. To medical men because it shows, as I have said, that ether and chloroform are dangerous anæsthetics, and it confirms the experience of every physician, that when such an unfortunate happening as this comes upon him, it is unexpected, and no matter what care he may use and what attention he may give to the case, such accidents do occur. It is a well-known fact among my friends that I am especially care-

ful about anesthetics, that I dread all of them. I never have a patient put to sleep without watching them personally, no matter who is my anesthetizer. My mind was on it, as well as the operation in this case, and I gave advice repeatedly during the administration of the chloroform as to the necessity of ceasing to give it or of giving a little more. The death in this case was truly and absolutely an unavoidable occurrence, such as may meet the physician any time and under any circumstances while using an anæsthetic. It shows the necessity of medical men fully protecting themselves against unjust suspicions and attacks on the part of any one, by never giving an anæsthetic, under any circumstances, unless one is able to prove that the circumstances attending the case were proper in every way.

MEDICAL PROGRESS.

Medicine.

THE OIL-SILK JACKET IN ASTHMA.—DR. S. C. BUSEY, of Washington, has used the oil-silk jacket in bronchial asthma with good results, and recommends it for further trial especially in that type of cases which is under the influencing control of climatic and atmospheric conditions. In the case of one patient the regularly recurring winter paroxysm has been apparently kept well under control whenever the jacket has been adopted at the onset of an attack: from October, 1889, to January, 1890, the jacket had been worn continuously; when it was removed, about January 1, 1890, because of the discomfort incident to a period of unseasonably warm weather. Since its last removal the patient has had numerous very slight attacks of dyspnea, coming on during the early morning hours but disappearing after sunrise; none of these attacks were noticed during the time of its being worn. How far idiosyncrasy influenced the good effects obtained by Dr. Busey, he admits that there is room for doubt, but the suggestion is offered by him in the good faith that the treatment may be tested by a more extensive trial, and thus found a useful expedient to some of those who suffer from asthmatic and bronchial complications.

FIBRILLARY CHOREA.—DR. MORVAN (*Gazette Hebdo.*) has observed five cases of peculiar fibrillary tremor to which he has given the name "*chorée fibrillaire*," and which he thinks constitutes a new clinical group. His first case was a young peasant who had always been well but who complained of a peculiar trembling in the buttocks and a general feeling of weakness. The tremor increased and involved successfully the thighs, back, shoulders and arms. The contractions were confined to the single muscle bundles and so did

not produce movements of the limbs: they were irregular so that the skin over the muscles rose and fell like the keys of a piano. The patient could perform all of the usual movements, and during voluntary contraction the abnormal ceased. The affected muscles were painful, and pain was felt in the legs when in the upright position. Temperature was normal but the pulse was very rapid. The contractions became more frequent and were especially marked in the buttocks and deltoid. The face, hands and feet remained free. Three weeks after the beginning of the disease albuminuria was found, and a few days later delirium came on and the patient died comatose.

Another case was that of a boy 16 years of age who had similar fibrillary contractions, especially in the buttocks and thighs. With the use of warm baths at the end of four weeks the contractions ceased. The disease returned early in the summer of each of the next three years.

A young woman, 23 years of age, was similarly affected, associated with general weakness and chlorosis. Recovery at the end of four months, and three years later a slight attack of the same trouble. Two additional cases are given, both young girls with a history similar to the one above described. In each of these the contractions were confined to the legs.

Surgery.

APHASIA DUE TO ABSCESS OF THE BRAIN.—SENGER and SICK (*Deutsche med. Wochenschr.; Centr. f. Chir.*, No. 40, 1890) report a case which is interesting because the location of the abscess in the posterior third of the left temporal lobe was diagnosed by the presence of sensory aphasia. The patient, a man fifty years of age, seemed to be suffering from some psychical trouble. He did not answer the questions which were asked him, but simply pointed to his left ear, which was so much swollen that the external meatus was nearly closed. In three days this swelling had become sufficiently reduced to reveal the discolored drum membrane, through a perforation in which a small quantity of foul-smelling pus escaped. He lay silent and not appearing to notice, but when excited he talked much in incomprehensible language. He could not give the right name to objects, but, instead, gave a roundabout description of them. The pulse was slow, 48 to 56 a minute; he suffered from headache, periodical vomiting, and stubborn obstipation. Finally a right-sided facial paralysis appeared, together with a weaker power of pressure in the right hand. The wife of the patient said that her husband had for several years had a discharge from his left ear, and for the last fortnight had complained of pain in the ear and headache. From these circumstances—that there was a chronic suppurative inflammation of the middle ear, acute symptoms of pressure on the brain, and

aphasic disturbance—the diagnosis of abscess of the brain in the posterior third of the first temporal convolution of the left side was made, and this diagnosis was confirmed by operation. The result of the operation was pronounced “ideal” nearly three months afterward, in spite of a small hernia cerebri which complicated the convalescence.

The writers maintain that only two cases have hitherto been reported in which the diagnosis of abscess of the brain was made from the presence of aphasia.—*N. Y. Med. Journal*.

CARCINOMA MAMMÆ.—BIHLER (*Münchener Dissertation*, 1890) reports the results of forty operations made by Angerer. In each case the entire gland was removed, and the axillary space was cleaned out whether the enlarged glands could be felt or not. In most of the cases the pectoral fascia was removed and in the later cases a portion of the muscle itself. In cases of relapse the masses, if movable, were removed with the knife, when the gland was affected, and with large tumors, they were excised with the thermocautery after the method of Nussbaum.

The results to date are: Dead 65 per cent., 12.5 per cent. live but the disease has returned. In 20 per cent. there has been no return of the trouble, among these are three in whom more than three years have elapsed since operation, and two in which more than two years have passed.

ACTINOMYCOSIS OF THE SKIN.—TILANUS (*München. Med. Wochenschr.*) reports a case in which the skin of the face was alone affected, the muscular structures and mucous membrane of the mouth remaining free. Two similar cases have been reported, one by Albert, the other by Majocchi.

The history of the case was briefly as follows: A young woman 22 years of age presented a swelling of the right half of the face that slowly increased and later opened in several places; finally the whole region from the external angle of the eye and including the side of the neck as far as the angle of the lower jaw. The skin of the part presented red prominent masses interspersed with patches of healthy tissue, with here and there an ulcer, which discharged a sero-purulent fluid. The few remaining teeth were carious and were removed. Treatment consisted in thoroughly curetting the affected skin, and free applications of a solution of corrosive sublimate.

The etiology of the trouble was obscure, but the author thinks the carious teeth played an important rôle in the production of the disease.

Dr. Lesser, of Halle, contributes to the *Arch. für Klin. Chir.* three cases of actinomycosis hominis in which the skin alone was affected. The first was that of a salesman 35 years of age

who had suffered from toothache for one year, and had eighteen extracted. For six months has had an ulcerated swelling of the forearm. A careful examination revealed similar ulcerations upon the right side of the head, in the right infra-orbicular groove, and the left side of abdomen.

A second was that of a 34 year old man, who for several days had presented two swellings on the right calf. The enlargements were painful and the patient had rigors with high fever. The subcutaneous lymphatics were not involved.

A third was that of a locksmith, who six weeks previously had been lightly burned upon the right leg. In this region a slight swelling appeared, which rapidly increased, followed by ulceration and the discharge of some pus.

All three cases made a rapid recovery after excision, curetting and cauterizing. The diagnosis in each case was confirmed by the finding the *strahlenpilz* in the discharges of the wound.

The author says that it is of special importance to note the great variability in the clinical picture presented by actinomycosis of the skin in man. At times the process may be sub-acute; again, it may be acute with marked disturbance of the general health. As a rule, swelling of the regional lymph glands is not present.

Obstetrics.

BROMIDES IN VOMITING OF PREGNANCY.—DR. WERTHEIMER, of Freiburg (*Centr. bl. f. Gynäk.*, December 20, 1890), describes the case of a woman, aged 33, who had borne eight children, who had required artificial abortion at the third and fourth month respectively in two labors, on account of uncontrollable vomiting. She once more became pregnant, and violent sickness set in only fourteen days after conception. No nourishment could be taken, and she soon became dangerously exhausted. Belladonna and morphine failed to influence the sickness. Bromide of potassium checked it slightly. Dr. Wertheimer then gave, every two hours, half an ounce of a mixture consisting of three parts of bicarbonate of soda, two of bromide of potassium, two of bromide of sodium, and one of bromide of ammonium, dissolved in thirty parts of syrup of orange peel, and one hundred and twenty of distilled water. The vomiting ceased, the patient's strength increased, and, at the time of the report, the patient had passed the fifth month of pregnancy without any return of the sickness.—*Brit. Med. Journal*.

TREATMENT OF PLACENTA PRÆVIA.—DRS. W. J. KOLFF and TREUB (*Nouvelles Archiv. d'Obstet.*, September, 1890) record the results of this malpresentation, as observed by them at Leyden. Between 1856 and 1879 26 cases of placenta prævia were noted by Dr. Kolff, with a mortality of 42 per cent. On the other hand between 1887 and 1889 Professor Treub has ob-

served 13 cases. In all of this series he performed combined version, losing only one patient. The fatal case cannot fairly be attributed to the method of delivery, for the woman died of pyæmic phlebitis, set up by a dirty sponge which the midwife introduced into the vagina to check the hæmorrhage before version was performed. Hence the mortality did not amount to 8 per cent. Of the children 8 (or 61 per cent.) died, but 4 must be subtracted as the heart sounds could not be heard before version; thus the precise mortality was 30 per cent. During childbed bad results were observed only in cases that had been previously examined by midwives, except in one instance, where the vagina had been plugged with sterilized absorbent gauze instead of iodoform gauze. The great principle of practice at Leyden is to separate version from extraction. The former is undertaken in order to save the mother. It is only in cases of subsequent hæmorrhage that extraction by the feet is carefully undertaken. Dr. Kolff praises that practice, as it renders interference practicable very early in the labor, before the mother is exhausted by hæmorrhage, saves her from the risks of prolonged plugging, and allows the later part of labor to continue slowly and yet without danger. The risk of *post-partum* hæmorrhage is thus greatly lessened. The risk to the child is theoretically great, yet the above statistics prove that the infantile mortality is not very high.—*Brit. Med. Journal*.

THE MANAGEMENT OF THE MENSTRUAL EPOCH.—DR. A. W. PARSONS, of Northampton, Mass. (*New York Medical Journal*), says: "During the past few months I have adopted a procedure which has afforded me the heartfelt gratitude of every woman who employs it. For obvious reasons its use will be largely confined to married women. A full-sized tampon of antiseptic cotton, to which a string is attached, is inserted into the vagina through a speculum as soon as the premonitory symptoms of the approaching menstrual epoch are noted. It may be left *in situ* for twenty-four hours, unless the uterine discharge begins, when it should be removed as soon as it is saturated, and the vagina washed out with a warm antiseptic solution by means of a fountain syringe, and a fresh tampon introduced. This procedure should be continued until the flow ceases. The principal disadvantage of this method is the difficulty of using the speculum and preparing and introducing the tampon; but I have met with no case where one or two lessons did not teach the woman the *modus operandi*. Its advantages are many. There is entire absence of odor, no necessity of wearing the napkin, and the sense of support to the uterus afforded by the tampon is immediate, and exceedingly grateful."—*Medical Record*.

Pathology.

RELATION OF STOMACH DISORDERS TO AFFECTIONS OF THE MALE GENITAL ORGANS.—PEYER (*Sammlung Klin. Vorträge*) claims to have demonstrated reflex neuroses of this kind in over 300 cases. He points out the close, and frequently observed connection between disease of the female generative organs and the stomach, and claims that a similar relation is to be observed in the male. The principal cause of these neuroses he finds in onanism, *abusus sexualis* and coitus reservatus. The symptoms relating to the stomach are atony, gastroplegia, nervous vomiting, eructations, cramps, and the secondary disturbances of these conditions. The diagnosis is oftentimes difficult, but may be made by the presence of the products of chronic urethritis (*urethral-faden*), and the so called *Hodencylinder* in the spermatic urine.

Therapy is to be especially directed to relieving the local sexual disorders, and the condition of the nervous system.

VIRULENCE OF THE SUPRA-RENAL CAPSULES IN RABIES.—BOMBICCI (*Riforma Medica*) has determined that the adrenals contain a considerable quantity of the rabic virus, though less than is found in the central nervous system. When portions of the capsules are injected into healthy animals it produces the characteristic phenomena of rabies, but the disease is milder than when portions of the cerebro-spinal axis are used.

The writer determined experimentally that there was a true ante-mortem accumulation of the poison in these organs, and not a simple post-mortem diffusion.

Bacteriology.

THE PRODUCTS OF PATHOGENIC BACTERIA.—During the past two years great progress has been made in the study of the action of pathogenic bacteria. This work has chiefly been carried on by Koch and Pasteur on the Continent, and by Drs. Sidney Martin and Hankin in England. In the *Revue de Médecine*, 1890, No. 7, DR. CHARLES BOUCHARD publishes an article on the properties of the substances secreted by pathogenic microorganisms. It contains the chief part of his address before the Tenth International Congress on the "Mechanism of Infection and Immunity." After an exhaustive summary of all that is known concerning the action of products of metabolism with which we are acquainted, Bouchard relates a series of thirty-one experiments which he made, partly in order to investigate the power which blood-serum possesses of destroying bacteria, and partly to ascertain how far their products confer an immunity against similar or other bacteria. Many experiments demonstrated the influence of the same products on phagocytosis. The space here is too limited to enter into the details of this interesting paper, but the general results of Bou-

chard's investigations are as follows: Among the substances secreted by the microbes are some which have an inhibitory action on them—that is to say, these products tend to retard the development, increase and characteristic action of the microorganisms; other substances are favorable to their growth. These, however, only act indirectly by modifying the material upon which they grow (peptones, etc.). Such products may be favorable or unfavorable for other microbes. Some organisms produce poisonous substances upon which depends their virulence. Amongst pathogenic microbes are some which secrete substances that confer upon animals inoculated with them an immunity against these particular germs; this they do not by their presence only, but by modifying the animal organism, so that it forms a less favorable pabulum for the development and growth of the bacteria, and causes the leucocytes to perform the process of diapedesis more rapidly, and to assume their functions as phagocytes more energetically. If an animal be inoculated with these substances, together with a pure culture of the same bacilli from which they were obtained, the disease runs a more rapid course, whilst its development will be delayed or prevented if the animal be inoculated a few days before the injection is made. If bacteria which act antagonistically towards one another be cultivated together in a test-tube, the soluble products of the "stronger" can be made to retard the development of the "weaker" organism. So that if an animal be inoculated with the products of metathesis of the "stronger" at the same time as the active principle of the "weaker," the action of the latter will be delayed and weakened. Some microbes appear to assist the action of others; these Bouchard terms "auxiliary microbes." By this means an animal may be infected with a disease which it would otherwise resist.—*Lancet*.

GERMICIDE ACTION OF THE GASTRIC JUICE.—In the *Wacht*, Nos. 38, 40 and 41, 1890, p. 894, Dr. BORIS I. KIANOVSKY, of St. Petersburg, publishes a valuable paper on the subject, embodying his elaborate experiments on fifty persons, some of whom were healthy, some suffering from gastric cancer, dilatation of the stomach, etc. The author's essential results may be summarized somewhat as follows:

1. A fasting healthy stomach always contains great numbers of microbes of various species.

2. The numerical strength of such microbes as are found in the gastric contents an hour or so after a meal stands in a direct relation to the number of microbes in swallowed food, drink, air, etc.

3. The gastric juice possesses distinct antimycotic properties, which are to be attributed mainly to the presence of a free hydrochloric acid.

4. "Given a gastric juice of a normal average

general acidity, and with a normal average proportion of free hydrochloric acid, the secretion kills the bacteria in a systematic manner—that is, the longer it remains in contact with the microbes the greater number of the latter are destroyed."

5. In the case of the juice of a subnormal acidity, however, the bacteria continue to steadily grow in number.

6. The microbes do not seem to take any part in the gastric digestion.

7. In such sick persons whose gastric juice still continues to contain a sufficient proportion of free hydrochloric acid, the secretion proves to possess the same germicide properties as in healthy people.

8. Such sick persons whose stomach elaborates but trifling amounts of free hydrochloric acid, are liable to be infected through the organ to a greater degree than healthy subjects.

9. "Nobody should allow his stomach to remain empty for a long stretch of time after morning rising; especially medical practitioners should take care in this regard."

10. "In times of epidemics (*e. g.*, cholera) everybody should avoid fasting for a long period. It is advisable to arrange one's meals in such way that the stomach could always contain a certain quantity of food (sterilized, if possible)."—*Provincial Med. Journal*.

MICROORGANISMS IN LEUKÆMIA.—DR. CLAUDIO FERMI (*Centralbl. für Bakt. u. Parasitenk.*, Band viii, No. 18, 1890) was able, some eighteen months ago, to separate from the enlarged spleen of a man, aged 55, who died of leukæmia, with enlargement of the various organs and of the peritoneal, mesenteric and axillary glands, pure gelatine plate cultivations of an organism which appeared as rounded or oval, white, non-liquefying colonies. Inoculated into gelatine in tubes, the growth appeared principally at the surface in the form of a milky-white, thickish layer, growing moderately rapidly, and gradually giving rise to slight liquefaction beneath. These colonies were made up of short, thick rods with rounded ends, the centre of the rod remaining unstained. At first he was inclined to assign no special rôle in the production of leukæmia to these organisms, but as he was unable to find them in similar positions in twelve other bodies that he examined—cases of pleurisy, meningitis, nephritis, sarcoma, diphtheria, tetanus and typhoid fever—he came to the conclusion that they must have some definite relation to the disease. Kelsch and Vaillard have since then shown that these organisms are pathogenic to rabbits, and that after the death of the inoculated rabbits they may be found in the blood.—*Brit. Med. Jour.*

THE HIGHLANDS OF MEDICINE.

There is a certain class of medical literature and teaching that is made so positive and dogmatic, as to create doubts and suspicions of its reliability. Many very good teachers err in supposing that unless they state the facts of medicine in the most positive way, it never can impress the student. Often medical text-books are written in this spirit, and students and readers who accept them as final, have much to unlearn in after life. While it is not quite true that the positive dogmatic man, on questions of science, *is a quack*, it is true that empiricism depends on the positiveness by which it is proclaimed. DARWIN expressed the truth when he said: "Ignorance more frequently begets confidence than does knowledge; it is those who know little and not those who know much who so positively assert that this or that problem can never be solved by science."

The leading teachers and writers in all the exact sciences, are particularly noticeable for their modest statements of facts, only claiming that from their experience and the evidence before them such facts appear to be true. Often these leaders of science differ widely, and the reasons for it are stated, and the facts become a matter of study and criticism, in a spirit and evident consciousness, that on wider knowledge may show the errors of both. This does not appear so clearly in the science of medicine. To-day there are far too many medical teachers, authors, and journals and books, that are down on the very

lowlands of science, who assume that a fact which seems apparent, is final and unchanging; that there are certain great basal truths in medicine absolutely fixed, and to these there should be a steady accumulation. To such men the science of medicine is merely a hunt for new fixed facts. If certain phenomena occur in their experience often, they conclude that it is an absolute fact, and become warm defenders of it. Such men never have broad comprehensive views of medicine. They do not realize that medicine like other sciences is still very far down, and in the infancy of its growth. The anatomy of the body, outside of a few facts, is unknown; practically the physiology is a mass of unproved hypothesis; the phenomena of disease and diseased changes are equally hypothetical and unknown. In chemistry, the atomic theory is still vague and uncertain, and altogether theoretical. In materia medica a most bewildering mass of statements and theories follow each other, like the shifting scenes of a panorama. Surgery and practice of medicine and all the newer theories that come up in a night, are like the troubled waters of the ocean, incessantly changing, and taking on new and old aspects. Yet with all these theories, and confused, hypothetical apparent facts, there is a tremendous movement towards some great central truth, or ranges of truths, which can only be seen from a higher point of view. Every medical man who has gone up far on the frontiers of medical research realizes this, and is startled by the fact that all this theory and hypothesis in medicine, are but stepping-stones and roads of advance, to be abandoned farther on. The physician who from his inner consciousness, or from a mass of statistics, brings out some new theory which is accepted because of its reasonableness, or the author's reputation, is sadly deluded if he supposes he has found a final truth. A few years and it is replaced by other wider theories, and if we believe the modern doctrine of evolution, this birth and death of theories is only the advance of mind towards the manhood and Godhood of the race.

These views are illustrated in the present excitement of a new remedy for consumption. Many of the journals, essays, lectures, and editorials, on this topic have startled the reader by their positive completeness, and clear conclusion that almost a millennium had arrived for the poor

victims of phthisis. Credulity and expectancy merged into sharp rivalry, to usher in this new era. The broad scientific statement of the discoverer that so far, there were many reasons for supposing that such and such results would follow the application of such and such means, and giving the experimental evidence on which he ventured such a general opinion, was the true voice of a scientist. While the positive excited statements which followed, were but the noise and roar of those far down in the valley, unable to comprehend what this master of research, had seen higher up.

Most of the real advances in medicine have come silently, and after a time it becomes difficult to find the exact source. Many real workers in different parts have reached similar conclusions, from different points of view, and from their quiet conservative statements, new ranges of facts have appeared. The noisy, assertive student who makes out a complete theory, and defends it sharply in journal or volume, is rarely a true scientist.

The medical man who is on the highlands of science to-day, is never dogmatic or positive, all his conclusions and opinions are stated as only apparent truths at present, but subject to constant revision and change, from the application of new facts and evidence. Medical science is really a study of the laws of human evolution and dissolution, and all our knowledge of necessity must be imperfect and open to error, and subject to constant change. What is most needed is a judicial analytical method of study. Not a crowding of statements and theories, but education of the mind to discern and compare the appearances and phenomena of human life. Hence positive text books, lectures, journals and essays which assume completeness, in their theories and statements, are obstructive to science. New discoveries, and new theories and methods of treatment, are to be welcomed always, but never as final absolute truths. If this could be realized literally, we should have no *fads* in medicine, no popular delusions or theories, that would die away only to give place to others. The bacilli and each new theory would pass the gauntlet of critical examination, and quietly take its place as an open door to wider realms of study. CARLYLE'S criticism is unfortunately not untrue, for many of the profession: "Doctors, like the masses

of mankind, keep down in the valley of knowledge and science; only a few ever climb up the highlands and see the race march with the eye of true science."

NON-ISOLATION IN TYPHUS FEVER.

DR. FÜRBRINGER reports to the Berlin Medical Society the principal data concerning the late epidemic of typhus fever in the city above named. The disease sprang up in January, 1890, and ran for a period of seventy-five days. There were, in all, 155 cases received at the hospital; 67 were males, 75 females, and 13 were children under 12 years. The deaths were males 12 per cent., females 8 per cent., and children 15.5 per cent. Many of the males who died had a history of excessive drinking. Isolation was not practiced with any rigidity, and yet no other patients contracted the fever; only four of the sisters of mercy took the fever, and one other attendant, with no deaths among the latter. The excreta were removed or destroyed without delay, and this Dr. FÜRBRINGER holds is the main point of prophylaxis whether in private or in hospital practice; in importance, it far outweighs all attempts at isolation. Forty-two of the patients, when convalescent, were sent to the convalescent homes, affiliated with the general hospital, and with good results. The above is a brief abstract from the Berlin letter to the London *Lancet*.

VARIOLA AND TUBERCULOSIS.

In the *British Medical Journal* of January 24, DR. LAWRENCE cites two instances of remarkable recovery from advanced stages of tuberculosis, seemingly as the result of virulent forms of small-pox. The patients, he says, were both young men in the last stages of pulmonary consumption. In each case there were large vomicae and the patients were much emaciated. Both the young men were attacked with virulent small-pox, with very high temperatures. They were supported with stimulants and a nourishing diet, and as they recovered from small-pox the pulmonary symptoms in each case began to disappear. They each made good recovery and are now in robust health. In these instances so well attested it becomes a question of deepest interest as to the manner in which such results were accomplished. Is there a small-pox bacillus which controls the situation, and is the weaker bacillus

of tuberculosis overpowered and driven out? or by reason of the new disease did the phagocytes take on increased activity and destroy the tuberculous bacilli? These questions raised by the writer are sure to attract attention and in our future bacteriological studies we must confront the question as to how tuberculosis is modified or controlled by small-pox, if such shall be found to be a fact.

EDITORIAL NOTES.

DISPUTED DIAGNOSIS.—At a recent monthly meeting of the Albany, (N. Y.) Health Board, Dr. Lewis Balch, the City Health Officer and Secretary of the State Board of Health, reported that during January 203 cases of typhoid fever had been reported to him, and that eighteen deaths had been caused by it. He, however, insisted that there was very little true typhoid fever among all the reported cases. Although admitting that it was more prevalent than usual, he said he did not know what to call the prevailing disease, but still inclined to the belief that defective drainage caused it.

Other physicians, however, hold that with but few exceptions the alleged cases of typhoid fever have occurred in a section of the city that is supplied with water from the Hudson River. As the fever has been prevalent in the cities up the river, which drain into it, the general belief is that the water has caused the disease.

TRAINED NURSING FOR THE POOR.—At Brooklyn, New York, there has been organized, on a small scale, a nursing department of the Red Cross Society. One district nurse has begun duty, and others will follow if the plan works satisfactorily; she gives her services free of all charge to those who are unable to employ a nurse. Her attendance upon the sick poor must be at the request of the attending physician, whose instructions are the invariable guide for her action.

THE EFFECTS OF KOCH'S LYMPH.—It is already evident that this liquid exerts a powerful pyrogenous influence, and is capable of exciting congestions throughout the whole system. It is stated by investigators that it is impossible to determine which organs shall most markedly feel its effects, and that in the same person different inoculations affect them differently. Diseased organs are most likely to suffer, but it is not

necessary that the affection shall be of tuberculous character. Organs apparently healthy may take on intense congestion. The lungs and bronchi are frequently found to be inflamed. Cases of myocarditis and endocarditis are reported in connection with the use of the "lymph." Swelling of the spleen, and albuminuria are reported as resulting from inoculation, and several cases of hæmaturia are reported as lasting from three to four days each. Evidently tuberculous subjects are not alone affected by the inoculation of the "lymph."

PASTEUR INSTITUTE AT NEW YORK.—The Directors of this institution held a meeting January 30, to receive the report of Dr. Gibier, regarding the proposed enlargement of his accommodations. The building now occupied, No. 178 West Tenth St., is most of the time over-crowded with patients, and almost daily applicants have to be turned away. The Directors voted to take steps to provide more commodious quarters without delay.

THE CHICAGO MEDICAL SOCIETY, whose action on the question of the removal of *THE JOURNAL* to Washington appears in this issue, has a membership of 494 members.

MEDICAL ITEMS.

A RECENT enumeration places the number of doctors in Vienna at 1,315, about one to every 1,000 of its inhabitants.

THE TUBERCLE BACILLUS seems to differ from the other bacteria from the fact that albumens alone are insufficient as nourishing media, but that the presence of glycerine and carbohydrates are essential to its growth.

THE DEATH OF SURGEON GENERAL BALFOUR, Honorary Physician to the Queen of England, occurred at Wimbledon Park January 17, at the age of 78 years. For many years, and nearly up to the time of his death, he had been a highly valued contributor to the columns of the London *Lancet*. He had held many important positions and was universally esteemed. The English journals have only words of sorrow and of profound respect for one who could remember Walter Scott, and Jeffrey and Allison, Chalmers, Wilson, Christison and, not least, John Brown, who wrote of "Rob and his Friend."

BACTERIOLOGICAL RESEARCH IN INDIA.—The

Provincial Medical Journal says we learn from the *Indian Medical Gazette* that Professor Lingard, who has arrived in India to take up the new office of bacteriological research at the Poona College of Science, has been appointed on the recommendation of Dr. Cook, after consulting the best authorities. The appointment is made on the basis of a three years' engagement, and the establishment of a new and fully equipped laboratory at Poona is an event of very considerable interest to the whole of India. Dr. Alfred Lingard has devoted many years to bacteriological science, and was a lecturer on the subject, both elementary and advanced, at the Birkbeck Institution, besides having also lectured on physiology. Before leaving Europe he visited the great Continental laboratories, including those of Berlin and Leipsic, for the purpose of inspecting the newest methods of research.

THE AMERICAN ELECTRO-THERAPEUTIC ASSOCIATION held its first meeting, for organization, at the New York Academy of Medicine, on Thursday, January 22d. Officers were elected as follows: President, Dr. G. Betton Massey, of Philadelphia; vice-presidents, Dr. W. J. Morton and Dr. A. H. Goelet, of New York; secretary, Dr. W. H. Walling, of Philadelphia; treasurer, Dr. George H. Rohé, of Baltimore; councillors, Dr. Horatio R. Bigelow, of Philadelphia, Dr. F. H. Martin, of Chicago, Dr. W. F. Hutchinson, of Providence; Dr. Frederick Peterson, of New York, and Dr. C. D. Palmer, of Cincinnati.

THE AMSTERDAM SOCIETY OF NATURAL HISTORY AND MEDICINE celebrated the centenary of its foundation on October 15th, when the gold medal awarded every ten years to the investigator who has done the best microscopic work in that time was presented to Professor E. Haeckel, of Jena, for his researches on deep sea zoology.

THE NEW BUILDING OF THE MEDICAL DEPARTMENT OF THE ARKANSAS INDUSTRIAL UNIVERSITY.—On the 5th ult. the elegant and commodious new building of the medical department of the Arkansas Industrial University was occupied for the first time. There was no unusual ceremony attending the event, but it marks an event of more than ordinary importance to the medical profession of the Southwest. For twelve years the school has occupied a handsome building in Little Rock on Second, between Louisiana

and Main Sts., but as the structure had been erected for other purposes, the faculty never felt quite comfortable in it, and long ago determined to build an edifice that would be a model of its kind—handsome, commodious, comfortable. The new college is on the corner of Second and Sherman streets, situated on a lot 50 × 100 feet, the building being 40 × 100, and three stories high. The first story has a large lecture hall capable of seating comfortably 250 students. In the rear of this are a number of rooms suitable for all the uses for which such apartments in a medical college are usually set apart. On the second story is the model amphitheatre, as capacious as the lower lecture room, and affording students every facility and comfort for witnessing surgical clinics and demonstrations of all kinds. Surrounding and in the rear of the operating amphitheatre are more rooms, well adapted for the uses for which each has been selected. On the third floor is one of the largest, best lighted, and most convenient dissecting-rooms to be found anywhere. The building is splendidly lighted and ventilated, supplied with water, gas and electricity, and has a fine elevation.

The lecture-room and amphitheatre are supplied with comfortable and substantial opera chairs. A contract has already been let for paving East Second street through its entire length. When this is completed the college will be pleasantly accessible by vehicle in the worst weather, as it is now by the street cars, which pass within one block. The patrons of the college have increased in numbers and intelligence every year, until at the present there are nearly a hundred students in attendance. The faculty have done their work conscientiously, quietly and well, and the thanks of the doctors in all this part of the country ought to be given them.—*Journal State Med. Soc. Arkansas.*

RESPONSIBILITIES OF THE RAILROAD SURGEON.—The services demanded by railway companies of their surgeons are most exacting. Railway injuries require immediate attention, whatever the needs of the surgeon's private patients may be. The injured employé is never backward in exacting services that cost him nothing. Under the impression that the company foots the bill he is determined to have all in the way of attention possible. The responsibilities assumed by the surgeon are of the gravest

nature. If the injured fails in making a case against the company, his next step is to commence action against the surgeon, if he can find some shyster of an attorney who can see his fees in the suit, and the cost of these suits must be borne by the surgeon, not the company. The order of skill required of the railway surgeon is of the highest. Of whom is demanded greater knowledge, experience and ingenuity than the surgeon called to attend the injured in a serious railway accident? Quick judgment, ready knowledge, a skilful, trained hand and eye are all requisite to one called upon to meet an emergency where injuries of every nature and extent are to be met with and their necessities relieved.—*Rail-road Age*.

IMPURE ICE AS A CAUSE OF DISEASE.—The State Board of Health of New York has come to the following conclusions as to the effects of impure ice in causing disease: "Ice formed in impure water has caused sickness; it may contain from 8 to 10 per cent. of organic matter dissolved in the water, and in addition a very large amount of organic matter that had been merely suspended or floating in it; it may contain living animals and plants ranging in size from visible worms down to the minutest spores, and the vitality of these organisms may be unaffected by freezing."

HOSPITALS FOR ALASKA.—Dr. Clarence Thwing, of Brooklyn, has accepted an invitation to establish one or more missionary hospitals in the Territory of Alaska, beginning at Sitka.

A BRITISH INSTITUTE OF PREVENTIVE MEDICINE.—Under the stimulus of the great discovery of Koch a kind of uprising has taken place in England in favor of an active physiological, pathological and bacteriological institute for research that shall be worthy to be called a national institution. At the head and front of this enterprise is Sir Joseph Lister, with numerous influential seconders, such as Sir Andrew Clark, Sir Spencer Wells, Sir George Paget, Sir James C. Brown, Jonathan Hutchinson, Ernest Hart, Professors Humphry Horsley, Watson Cheyne, Ray Lankester, Huxley, Sir Henry Roscoe and C. S. Roy. The exact nature and scope of the work carried on in the institute will necessarily depend on the liberality of the public subscribers to the fund or on the support granted by the government; but if possible it is proposed that the new

institute shall be on the same general plan as the Institut Pasteur, which is also the plan upon which the new institute for Koch is in process of building at Berlin; that is it will not be exclusively for research on the infective diseases of man and animals, but also for providing inoculant material for such diseases as tuberculosis, hydrophobia or anthrax. The Executive Committee has already sent their representative, Mr. E. H. Hankin, to Berlin for the purpose of learning directly from Koch the method of preparing the antituberculous lymph; Mr. Hankin has already made an enviable name for himself by his original work on the means of conferring immunity against anthrax. He is already at work at Koch's laboratory.

THE ELECTRIC LIGHT.—It is currently reported that the Queen of England has discontinued the use of the electric light in her private apartments, on the ground that it is injurious to the eyes. We are inclined to believe that this is founded on some misapprehension, for when properly protected by opal glass or by shades, the electric light can be toned down to any desired extent, and it certainly possesses many advantages over gas. It is more easily lighted and extinguished, less dangerous, more cleanly, free from odor, gives off little heat, does not spoil the air, is quite as steady, and, so far as we can see, has only one drawback—that, namely, of being more expensive.

THE IMPERIAL RUSSIAN INSTITUTE OF PREVENTIVE MEDICINE.—The Institute of Experimental Medicine, founded in St. Petersburg by Prince Alexander Petrovitch, of Oldenburg, at a personal cost of about 200,000 roubles (£23,000), was formally opened and handed over to the Imperial Government on December 20. The ceremony, which partook largely of a religious character, was attended by the Ambassadors, several members of the Czar's family, and by M. Chamberland, representing M. Pasteur; Dr. Pfuhl, representing Professor Robert Koch; and Mr. Watson Cheyne, representing Sir Joseph Lister. The Prince of Oldenburg was thanked by imperial rescript and appointed Governor of the Institute, and the three delegates having delivered brief addresses each in his own tongue, the proceedings terminated with an entertainment given at the Oldenburg Palace.

TOPICS OF THE WEEK.

THE ETHICS OF EXPERIMENTATION UPON LIVING ANIMALS.

Cruelty may be defined as the infliction of suffering without sufficient reason. To be humane is an expression of the highest type of manhood. And surely less inhumanity can be traced through the records of science, than can be found in the annals of either religion or philosophy. Who is more altruistic, more practically philanthropic, than a physician of the better class in his daily intercourse with suffering mankind? Yet these men are periodically assailed by well-meaning if not well-informed persons, and stigmatized as wantonly cruel for performing what, in the majority of instances, are but painless operations upon otherwise useless animals. An action is good, bad or indifferent, in direct ratio to its consequences. Now, those best able to judge admit that vivisection furthers the progress of scientific investigation, and, therefore, concede its defensibility. At the same time, when merely a matter of idle curiosity, it is held to be most reprehensible. Frequent repetition of painless experiments, however, finds its justification in the necessity for objective instruction. No person will deny that science has conferred incalculable good upon mankind. Nay, more, the burdens of the lower animals are daily being lifted by this modern offspring of the human intellect. Were it not possible to specify an individual discovery directly due to vivisection, nevertheless the fact would remain that the crucial test of all hypotheses is, experimentation. And it was not until verification became the anchor of all research that knowledge ceased to drift hither and thither upon the treacherous sea of speculation. But one of the most important steps in the advancement of physiological inquiry, the discovery of the inhibitory function of the pneumogastric nerve by Weber, was the result of an experiment upon a living animal, and it could have been demonstrated in no other manner. Moreover, this same method, in the hands of Pasteur, has bestowed sufficient benefit upon the animals themselves to more than compensate for the suffering inflicted upon them in the interest of science.

Unbridled Nature is the personification of cruelty, and the few victims of scientific investigation that are sacrificed for the welfare of man are as nothing compared to the multitude that meet with apparently purposeless destruction. Certain facts are beyond the reach of the physiologist, except through these experiments; but since, in many instances, pain is a disturbing element, its abolition may be relied upon from this, if from no higher motive. The highest order of man feels unwilling to inflict needless suffering upon any living creature. How much right we have to the lives of the lower animals remains an open question. And though, at this stage of our civilization, it seems to be the general opinion, at least as expressed by man, that the animal shall be slain for our needs, still the causing of unnecessary pain is justly reprobated. Nearly all vivisections, assuredly in our country, are performed after the animals have been rendered insensible; but where sentiment

blindly forms convictions, reason appears to hold no sway, hence, despite the facts of the case, these perennial crusades against a very necessary method of experimentation. Ultra-humanitarianism in its opposition to scientific advancement is liable to lapse into insipid sentimentality.—Dr. Stephen S. Burt in *The Post-Graduate*.

THE CURVE OF HEALTH.

Oliver Wendell Holmes says in the *Atlantic Monthly*: Let me tell you one thing. I think if patients and physicians were in the habit of recognizing the fact that I am going to mention both would be gainers. The law I refer to must be familiar to all observing physicians, and to all intelligent persons who have observed their own bodily and mental conditions. This is, the curve of health. It is a mistake to suppose that the normal state of health is represented by a straight horizontal line. Independently of the well-known causes which raise or depress the standard of vitality, there seems to be—I think I may venture to say there is—a rhythmic undulation in the flow of the vital force. The "dynamo" which furnishes the working powers of consciousness and action has its annual, its monthly, its diurnal waves, even its momentary ripples, in the current it furnishes. There are greater and lesser curves in the movement of every day's life—a series of ascending and descending movements, a periodicity depending on the very nature of the force at work in the living organism. Thus we have our good seasons and our bad seasons, our good days and our bad days, climbing and descending in long or short undulations, which I have called the curve of health. From this fact springs a great proportion of the errors of medical practice. On it are based the delusions of the various shadowy systems which impose themselves on the ignorant and half-learned public, as branches or "schools" of science. A remedy taken at the time of the ascent in the curve of health is found successful. The same remedy taken while the curve is in its downward movement proves a failure. So long as this biological law exists so long the charlatan will keep his hold on the ignorant public. So long as it exists the wisest practitioner will be liable to deceive himself about the effect of what he calls, and loves to think are, his remedies. Long-continued and sagacious observation will, to some extent, undeceive him; but were it not for the happy illusion that his useless or even deleterious drugs were doing good service many a practitioner would give up his calling for one in which he could be more certain that he was really doing good to the subjects of his professional dealings.

BARON HAUSSMANN.

The death of Baron Haussmann, recorded recently, is not only a political event, but concerns all who are interested in the cause of sanitary reform. From 1853 to 1870 Baron Haussmann held the reins of office as Prefect of the Seine; and, in those days of absolutism, there was no popular control to check his actions. The Emperor Napoleon III gave him a free hand, and he set to work, regardless of expense, to regenerate Paris. Broad boulevards were cut right through overcrowded districts,

Light and air were let in upon quarters where epidemic diseases had become endemic. So mighty were the changes wrought, that a new word had to be coined to describe the work, and all Europe talked of the Haussmannization of Paris. The great changes effected have not, however, proved an unmixed blessing. The financial situation they created supplanted M. Jules Ferry with the materials for the pamphlet which first brought him into political fame, and which he humorously entitled "Les Comptes Fantastiques de M. Haussmann." The debts then incurred are now so great a burden that they prevent the realization of sanitary reforms more urgent than those achieved by Baron Haussmann. It is not for us to criticise the artistic faults and merits of the new Paris Baron Haussmann built. The æsthetic side of the question is not our phase of the subject. Though opinions widely differ among artists, sanitarians can only mete praise for the giving of lungs to the town by creating the beauties and attractions of the Bois de Boulogne and the Buttes de Chaumont, etc. The splendid markets, slaughter-houses, and similar buildings of public utility Baron Haussmann caused to be built, have greatly contributed to the improvement of public health. But, on the other hand, there can be no doubt as to the evil tendency of sacrificing to external appearances financial resources that should be devoted to internal improvements. The magnificent dwellings raised on the new boulevards are constructed in defiance of all laws of hygiene, while but little was done to improve the sanitary condition of the old houses left standing. Judged by external appearances, nothing can be more vast, more splendid and sweeping than the new thoroughfares pierced by Baron Haussmann. The eye is fascinated, the imagination exalted, by these changes, realized so rapidly as to suggest the wave of a magician's wand rather than the slow evolution of municipal progress. But there is a theatrical element about this that fails to satisfy the scientific mind. The worse consequence, however, was the spread of Haussmannization to provincial towns, and especially to health resorts. For instance, at such towns as Cannes, Nice, etc., the public money was freely spent to cut broad boulevards, to raise handsome theatres and casinos, but the sewers were left in a deplorable condition, and domestic drainage utterly neglected. To the credit of the Third Republic it must be acknowledged that more interest is now taken in real sanitary improvements and less is expended on mere external show. Nevertheless, and in spite of all and numerous criticisms to which Baron Haussmann exposed himself, he gave an immense impetus to the cause of municipal progress. All the errors, the extravagances committed, the political motives that may have inspired some of the improvements initiated by Baron Haussmann, will not suffice to efface the glorious record of great works achieved by the late Imperialist Prefect of the Seine.—*Lancet*.

PROGRESS OF CREMATION IN ENGLAND.

The Cremation Society of England has now existed seventeen years. The crematorium and the building at Woking have been thoroughly tested, and are in every

respect efficient and commodious. The appearance they present to the eye—a combination of early Gothic architecture, extremely well executed, surrounded by beautiful trees and shrubs—is, especially in summer time, picturesque and pleasing. During the past year no fewer than fifty-four bodies have been cremated. Among them may be named the late James Nasmyth, the distinguished engineer, a generous supporter of the Society; the well-known Rev. J. MacNaught, of Liverpool; and the late Baron Huddleston, on which last occasion the service, performed in the Society's chapel by the Rector of Ascot, was attended by a distinguished assembly of relatives and friends. The Society is earnestly asking for support to complete their plan of erecting cloisters for the reception of cinerary urns. For this, and also for the purpose of promoting the interest of cremation, by publishing, lecturing, etc., the Council of the Society earnestly appeals to the public for donations and annual subscriptions. It may be as well to add that a payment of ten guineas constitutes the donor a member for life, and entitles him to be cremated without charge after death. Since the beginning of the present year, 1891, the remains of Kinglake, the historian, and of his Grace the Duke of Bedford, K.G., have been cremated.—*British Medical Journal*.

DR. KOCH.

Dr. Koch is 47 years old. After graduating at the University of Göttingen, he commenced practice in a little village near Hanover, but failed to make a living. He then tried Rackwitz, a small malarious town in Prussian Poland, with no better results. Finally he settled in Wollstein, and in 1880 attracted much attention by his analyses and medical testimony in the famous Speichert poisoning case. In 1882 he discovered the bacillus of tuberculosis, and in 1883 the germ of cholera while acting as the head of the medical commission sent by the German Government to Egypt and India to study the causes and prevention of cholera. On his return to Germany he received an honorarium of 100,000 marks, the rank of Privy Councillor, and the Rectorship of the Imperial Institute of Hygiene.

DEATH AFTER INOCULATION FOR LUPUS.

Dr. Janisch reports in the *Wiener klinische Wochenschrift*, No. 50, a case of death in a girl of 17, after a single injection of two milligrams of Koch's lymph. Local reaction had been very prompt. The injection was made at nine o'clock in the morning, and by three in the afternoon the region of the affected portion of the face was swollen, turgid, and surrounded by a bright red inflammatory zone of the width of the finger. The upper lip was livid. These local manifestations became more pronounced, and by the next morning the swelling had become more diffuse. The bright red had given place to a livid color, and in many places yellow crusts were noticeable. Dyspnoea came on, weakness of the heart, and death on the same evening, thirty-six hours after the injection.—*Medical Record*.

PRACTICAL NOTES

CURE FOR MORPHINISM.

W. I. Cattel during the past six years has had excellent success with the following formula: A mixture from which the patient is easily weaned, when the opiate is withdrawn (*Am. Pract.*).

Morphia sulphate or tincture of opium, q. s.
Fluid extract viburnum prunifolium, $\frac{1}{2}$ oz.
Elixir of ammonium valerianate, 3 oz.
Elixir sodium bromide (5 grains to the dr.).
q. s. to make 6 oz.

Dose, a teaspoonful when required. In smell and taste this mixture is truly diabolical, and many patients are glad to give up the horrible stuff long before the opiate is entirely excluded.

EPILEPTIC MIXTURE.

R. Potass. bromidi, } $\bar{a}\bar{a}$ gr. x.
Sodii bromidi, }
Ammonii bromid., gr. x.
Sodii bicarb., gr. ij.
Liq. potassii arsenit., m. j.
Aque., ad. $\bar{5}\bar{j}$. \mathfrak{m} .
S. Dose, $\bar{5}\bar{j}$.

—*Phar. Record.*

INHALATION IN WHOOPING COUGH.

R. Thymolis, gr. xx.
Acid. carbolic, }
Ol. sassafras, } $\bar{a}\bar{a}$, f $\bar{5}$ ij.
Ol. eucalypti }
Picee liquidæ }
Ol. terebinthinae }
Aetheris, f $\bar{5}$ iv.
Alcoholis, q. s. ad. f $\bar{5}$ iij. \mathfrak{m} .

Put about 30 drops upon a pad of such a size as to be conveniently hung around the child's neck, renewing the application every two or three hours.

In severe cases the inhalation treatment is supplemented by the internal administration of

R. Acid. carbolic grs. iij.
Sodii bromidi gr. i.
Tinct. belladonnae gtt. xx.
Glycerini, f $\bar{5}$ iij.
Aque., q. s. ad. f $\bar{5}$ ij. \mathfrak{m} .

Sig. Teaspoonful for a child, 3 or 4 years of age, occasionally.

—Dr. Beall, *Daniel's Med. Jour.*

BISMUTH TREATMENT FOR BURNS.

Dr. Bardeleben, of Berlin, recommends (*Therapeutic Gazette*, November, 1890), the following treatment based on an extensive experience: Wash the burn with a 2 or 3 per cent. solution of carbolic acid, or a 3 in 1,000 solution of salicylic acid. A little later open the blisters and cover the entire surface with bismuth subnitrate in very fine powder, and over this a thin layer of absorbent cotton. Renew the dressing as often as needed, which means to keep the parts dry and

free from the discharges of the wound. If the burn is very extensive, an ointment of bismuth is sometimes substituted for the powder.

ECZEMA.

R. Zinci oxidii, 1 ounce.
Glycerinae, 2 ounces.
Mucilag. acaciae, $\bar{a}\bar{a}$, 2 ounces. \mathfrak{m} .

In extensive patches of eczema this paste is very agreeable. If itching is severe 1 per cent. of carbolic acid may be added.

—*Courier of Medicine.*

AN OINTMENT FOR CARBUNCLE.

R. Ichthyol, 1 drachm.
Cauphorated lard, $\frac{1}{2}$ ounce. \mathfrak{m} .

This salve is to be applied three times a day around the inflamed area, and if the surface has become broken the tissues are to be touched with nitrate of silver. It is said that the ichthyol diminishes pain, favors the resolution of the swelling, and aids in cicatrization.—*Medical News.*

PEROXIDE OF HYDROGEN IN CUTANEOUS THERAPEUTICS.

Unna is quoted by the *Canadian Pharmaceutical Journal*, as recommending the treatment of comedones by the following prescription:

R. Sol. hydrogen peroxide
Vaseline, of each 2 ounces.
Lanolin, 1 ounce.
Acetic acid, 1 drachm.
Mix thoroughly and perfume as desired.

DELIRIUM TREMENS MIXTURE.

R. Potass. bromid. } $\bar{a}\bar{a}$ grs. xv.
Sodii bromid. }
Chloral. hydrat., gr. x.
Tinct. zingiberis, m. x.
Tinct. capsici, m. v.
Sp. ammonii arom., $\bar{5}\bar{j}$.
Aque., q. s. ad. $\bar{5}$ ij. \mathfrak{m} .
S. Dose, $\bar{5}$ ij.

—*Phar. Record.*

VOMITING IN PREGNANCY.

R. Bicarb. soda, grams 3.
Potassium bromide, grams 2.
Sodium bromide, grams 2.
Ammonium bromide, grams 1.
Syrup. aurantii carb., grams 30.
Aque distillate, grams 120. \mathfrak{m} .
S. Tablespoonful every two hours until relieved.
—Dr. Wertheimer.

INDIGESTION WITH FLATULENCE.

R. Bismuth subnit.
Sodium bicarb.
Sacch. alba.
Pulv. acacia.
Pulv. zingibri, $\bar{a}\bar{a}$ $\bar{5}\bar{j}$. \mathfrak{m} .
S. Teaspoonful of the powder dissolved in a little water after eating.

SOCIETY PROCEEDINGS.

Gynecological Society of Boston.

The 215th regular meeting of the Gynecological Society of Boston was held at No. 19 Boylston Place, on Thursday, Oct. 9, 1890, at 4 o'clock p.m., with the President, W. SYMINGTON BROWN, M.D., in the Chair.

Thomas P. Jefferson, M.D., of Lowell, Mass., was elected to active membership.

Joseph Eastman, M.D., of Indianapolis, Ind., was elected to corresponding membership.

DR. HENRY O. MARCY read a paper entitled

IN WHAT CLASS OF WOUNDS SHALL WE USE DRAINAGE? AND THE PRESENT POSITION OF ANTISEPTIC SURGERY.

(See page 229.)

DR. FRANK L. BURT said it is very evident that whether we drain or not depends altogether on the case. We cannot treat all cases after the same method, yet it is desirable that we find as good a method as possible and use it till we find one decidedly better. There is no doubt that many cases are drained which should rather be curetted thoroughly, so as to remove all diseased tissue and the surfaces be brought together by subcutaneous suturing so as to get healing by first intention. Tissue around a fistulous tract should be removed and treated in this manner. Some abscesses, fistulas, tumors of the breast, operations on hernia, etc., can be treated in this way without drainage. Care should be taken against too much tension on the skin and draining the sutures so tight as to strangle the tissues. Oozing of blood underneath the skin does not need to be removed by drainage if it is from a surface which is aseptic. It is not always necessary to provide for clots of blood by drainage as, if aseptic, they need not cause sepsis and may organize or be absorbed. Many who formerly used three or four tubes in breast cases now use only one. In my later cases I have used no drainage and have been better satisfied with the results. I advise closure of the surface entirely as I have described before. In abdominal surgery we will find that some cases require drainage while others do not. Some surgeons do not drain at present as often and in such cases as in the past.

If there are many adhesions giving rise to a considerable oozing, drainage may be necessary. Also bad cases of pyosalpinx or abdominal abscess may cause the operator to feel easier if drained. If blood oozes into the abdominal cavity or pus enters it, as thorough a removal as possible by means of absorption had better be done first.

There are cases which seem to require flushing with hot water. In case this is done, care should

be taken lest some of the pus or debris which is localized should be washed up among coils of intestines causing mere points of sepsis. When there is pus or much blood so that flushing is required, drainage had better be used. Glass or rubber tubes are serviceable. The fluid which accumulates should be removed frequently by absorption, cotton on a wire being introduced into the tube, or if a rubber tube is used, which seems to me preferable, the contents can be sucked up with a syringe.

It may be supposed that the abdominal wounds would require drainage as much as any, but if closed properly, the method of suturing in layers with animal ligature being the best, no drain is necessary and the surfaces adhere perfectly. It is very evident that a great advance has been made of late in respect to this subject of drainage.

DR. CHAS. K. CUTTER, of Charlestown, a guest of the society, said that in his opinion, locality has a great influence on the presence of germs, e.g., in the poorer quarters of the cities wounds do not do as well as in the country where there is less dust and other material floating about in the air. Although he regards cleanliness as an essential feature, he could not help recalling operations in which he had formerly assisted a Charlestown physician who had sometimes opened the abdominal cavity without even taking the natural precautions of washing his hands and no antiseptics were used. He remembered one operation in which four assisting physicians had successively introduced their fingers into the wound to establish a diagnosis and the patient recovered. He always uses drainage after opening a mammary abscess. He referred to the remarkable antiseptic properties of Merck's new substance, pyoktanin, and spoke of several instances in which he had seen it successfully applied.

DR. GEO. W. JONES said that he had been much interested in the paper, and that he agreed with the ideas of Dr. Marcy on the matter of drainage as expressed therein.

DR. A. L. NORRIS said that he had of late used drainage very little indeed, and if he has had recourse to anything he has used for this purpose a few strands of catgut ligature. He referred to the operations which he had seen Mr. Tait perform in Berlin.

DR. C. E. PRIOR said that he had watched with much interest the wordy war which has been waged over antiseptics. He believes that the followers of both Tait and Lister are on the same ground however much they may seem to differ. Both cleanliness and excellent surgical skill are essential to good results.

DR. JAMES P. ELLIOTT believes that both cleanliness and good judgment are necessary to obtain union by first intention.

DR. C. W. STEVENS thinks that the statement

that all abscesses should be drained is too broad. Large ones should be drained, but small ones should not. It is possible to withdraw the pus by means of a hypodermic needle, after which the cavity can be washed out with a solution of corrosive sublimate, 1 to 4000, and then with iodoform emulsion.

DR. A. E. McDONALD recently treated two abscesses on the same child. The one treated with drainage did better than the one treated without drainage.

DR. H. C. WHITE said that Dr. Marcy gives his opinions boldly and clearly, and that his success in treating wounds is due to the same boldness and clearness, as exemplified by the closure layer by layer, even the edges of the skin being accurately approximated. There can hardly be hemorrhage possible when the operation is done in this way. Perfect coaptation just tight enough and not too tight is important. The discussion between Tait and Lister is now chiefly of words and not of opinions. Both believe in clean aseptic wounds. Marcy has made advances and got ahead of his teacher, Mr. Lister.

DR. W. S. BROWN said that Sir Joseph Lister's modesty and thorough honesty is admirable.

DR. MARCY in closing the discussion said that he had seen much of these men (Tait and Lister) during the past summer. They have agreed to disagree. Tait has fought every one who has disagreed with him. Dr. M. believes that Tait is now broadening in spirit.

PATHOLOGICAL SPECIMENS.

DR. BURT presented a specimen of double ovarian tumors. The case was of special interest because of the difficulty of diagnosis. It had been considered for several months as a case of version which did not improve under treatment by means of applications, tampons, pessaries, etc. The uterus was found rather high up, toward the right and forward. The left ovary could be outlined, enlarged to the size of an egg, and somewhat prolapsed. No ovary could be detected on the right side. A mass, the size of a fetal head, was found behind, below and to the left of the uterus, seeming to be in the left broad ligament. This large mass was the right ovary with cyst, which, being displaced had become adherent so as to appear to be on the left side. The relief after operation was as usually experienced in such cases.

DR. IGNACIO MARTINEZ, of Laredo, Texas, at one time a general in the Mexican Army, a political exile, a great traveler and an author of ability, while making the rounds among his patients on the morning of February 3, was waylaid by two mounted men near the Mexican National Depot and shot to death. The assassins, supposed to have come from Mexico, escaped.

SPECIAL CORRESPONDENCE.

Hypnotism—Facts and Reports of Cases in the Early Experience of one of its Former Practitioners.

To the Editor:—Several articles have of late appeared in THE JOURNAL upon hypnotism, and there seems to be a general interest among the profession upon this subject. Though a permanent member of the American Medical Association for many years, and an attentive reader of every number of THE JOURNAL, I have never contributed anything to its columns. I come forward now and offer this communication with great reluctance and only because I deem it a duty to my professional brethren, to give them some benefit of my investigations and experience in the therapeutic application of this potent and subtle agent.

In the year 1841, while an under graduate and a hospital attendant, in the ward where I was employed one of the patients was a sea captain, whose home was in an obscure New England town. This captain conceived a strong attachment for me, and when ready to leave for home, insisted that I should accompany him. Being weary with several months' close confinement, I obtained leave of absence and went. Once there, he dubbed me "Doctor" and introduced me as such to his neighbors and some three or four practicing physicians in his own and surrounding hamlets.

I was soon called upon to treat the sick and was compelled to engage in practice, or to ignominiously desert my friend and forego his hospitality. I chose the former. This I did by the advice and promised aid of one of the most skilful and popular physicians in that neighborhood.

This physician, in addition to the usual drug treatment, practiced hypnotism, or as it was then called, mesmerism, or animal magnetism. Becoming close friends, we spent much time together, visiting patients and receiving and imparting information. One of the most fruitful subjects of our discussion was animal magnetism, and he finally persuaded me to engage in experimental examination of it.

By his instructions and assistance, I was soon not only practicing medicine but mesmerism as well. For five years that followed I was one of the most industrious practitioners of the healing art in that section of the country. Then, my trusted friend, teacher, and confederate suddenly departed between two days, leaving a wife and children unprovided for, but taking with him one of his female mesmeric subjects. This occurrence was an overwhelming blow to me, and gathering up my available means departed; attended medical college, graduated and wended my way westward, and have since pursued the regular practice of medicine. Since that time I have never publicly practiced, or advocated hypnotism under any of its aspects or names.

This narrative seems a necessary introduction to what I wish to contribute for the benefit of those who are interested in, and are now investigating modern hypnotism.

Had I made and preserved full notes of all the cases I treated by this agent, in those five fruitful years, I would be able now to give many interesting and instructive facts and cases that, in the lapse of nearly half a century, have either entirely faded from my memory, or become so much obscured as to render an accurate account of them now impossible. Many of these cases, their treatment and the results are, however, indelibly impressed upon my memory; and from these I can bring a sufficient variety and number to illustrate the more important and prominent qualities of therapeutical hypnotism.

Case 1.—During the prevalence of an epidemic of malignant dysentery, a lad of 9 years of age affected with

this malady had been given up as incurable by physician and family and not expected to survive the ensuing night. The boy insisted that I should be called, and on reaching his bedside and making a careful examination, I told him if he could yield to me and sleep, I thought he would recover. Placing one hand on his abdomen and the other on his head, I exerted all my will power in the effort to hypnotize him. The terminus soon grew less, restlessness abated and in half an hour he was hypnotized. I sat by his bed and kept him asleep for six hours. On awaking a bilious evacuation followed, with neither blood nor mucus. I then again hypnotized him and kept him asleep the whole night. He awoke in the morning more decidedly convalescent, rapidly recovered with no medication, except some placebos and proper diet, and is living to-day, a man of wealth and influence in both Church and State.

Case 2.—A young lady, about 19 years of age, had been under treatment for more than a year, by two good physicians, and was considered incurable. Her disease was a very severe case of bronchitis, thought to be of tubercle origin and her lungs already involved. She coughed almost incessantly while awake and did not sleep to exceed thirty minutes at a time, on this account, was expectorating freely and rapidly emaciating. At this stage of her case I was called in to make a trial of hypnotism. After a few sittings she was profoundly hypnotized—the constant cough and expectoration greatly interfering in its accomplishment. I kept her asleep some two hours at first, during which there was neither cough or expectoration. Gave her daily sittings gradually prolonging the period of sleep, then leaving her in that condition with instructions to wake at a certain time, which she always did. Then I changed the sittings to the hour of bedtime and told her to sleep till morning. While this treatment was progressing there was a constant daily improvement in all her symptoms. At length she was so much under control that she would obey me by falling asleep at a future hour and remaining in it as long as directed. Finally she would fall asleep and wake on specified times, each day, for three days in succession, without being visited, which greatly lightened my labors. In less than three months a perfect cure was effected in this aggravated case, without any medication; and I may add that more than thirty years afterward I saw this patient with husband and grown children, a perfect picture of health, and was assured by her that she had not in all these years suffered from any disease whatever.

Case 3.—A middle aged man, far advanced in pulmonary tuberculosis, applied to me for hypnotic treatment. On examination I told him there was no cure known for his case. He replied that he was fully aware of that, but from what he had learned, thought his condition and sufferings might be ameliorated by hypnotism. I found him an easy subject and hypnotized him daily for several weeks, and every sitting improved his condition. The small hemorrhages, of which he had many at short intervals, ceased. The amount of pus expectorated decreased; night sweats and diarrhea disappeared; digestion improved and he materially increased in flesh and strength. I found the treatment of this case very exhausting to me and a severe drain upon my vitality. I lost flesh and strength and other symptoms alarmed me and caused me to suspend my hypnotic efforts in his behalf. With some medication, he went on improving for a time, and he thought he was recovering. Several months afterwards, while fishing in a skiff, he hooked a very large one, and in the effort to capture it a violent hemorrhage came on and he died before his companion could pull the craft to land.

Case 4.—A married woman, about 50 years of age, after a long seige of house cleaning, received a severe mental shock. She was seized with a sudden and severe chill followed by fever and delirium. The next day she was violent and unmanageable and I was called. It was then a case of acute mania. I had hypnotized her some years

before, and after a persistent effort finally engaged her attention and soon had her under hypnotic influence, in which condition she was put to bed and kept in it under observation for fifteen hours, all this time remaining perfectly quiet. Her temperature, pulse and respirations gradually returned to normal. Before awakening she was told and impressed that she must take absolute rest for a week, and only think of the painful occurrence that gave her the shock as something that happened long ago. After she awoke she remained quiet and self-possessed, and made a speedy and complete recovery without any medication.

Other cases might be given, but these will suffice for the present.

This narrative and report of cases are but an introduction or preface to the subject, as it appears to me. The field is broad and fruitful and will amply repay the careful and thorough explorer. If those members of the profession who are interested in this subject desire it, more may be said, in which the principles, modes of application, the possibilities of its therapeutic employment, and the moral and physical responsibilities resting upon those who would practice it, will be discussed.

M. F. BASSETT, M.D.

Quincy, Ill.

Chronic Acid Treatment of Chronic Enlargements of the Tonsils.

To the Editor:—Miss G. M., act. 17, very small in stature, been delicate for several years. Tonsils very large, caused breathing through the mouth nearly entirely. They pressed against each other closely. Made a puncture with a small bistoury in one tonsil, then with a regular acid probe I heated or melted chronic acid crystals over a gas jet, until I had a nice smooth ball about the size of a small pea, which I carried into the punctured tonsil. Letting it remain a very short time after taking the probe out, I took up all excess of acid about the tonsil with absorbent cotton. The third day the patient presented herself with a large, deep slough from the centre of tonsil. After that healed I repeated the operation in the other tonsil, and continued until I had reduced them three fourths their size. I have used this remedy in six or eight equally severe cases, and with equally good results. Let us know if others have had a like experience. Mine were cases where the patients would not submit to excision. As there was no pain with this mode of treatment, it may commend itself to others where surgical procedure is denied.

F. E. YORUM, M.D.

Shreveport, La.

Shall The Journal be Removed to Washington?

THE ACTION OF THE CHICAGO MEDICAL SOCIETY.

To the Editor:—At the January 14 meeting of the Chicago Medical Society a committee was appointed to consider the matter of removing THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION from its present location. After considering the matter the committee reported at the February 2 meeting and recommended the passage of the following resolutions, which were unanimously adopted:

Resolved, That the Chicago Medical Society as a body is opposed to the removal of THE ASSOCIATION JOURNAL deeming that such change is unnecessary at the present time and contrary to the best interests of THE JOURNAL and the Association, and be it

Resolved, That the delegates from this Society to the forthcoming meeting of the American Medical Association be and are hereby instructed to oppose such removal and be it further

Resolved, That the committee appointed at the last meeting be continued to take such action as they deem wise in furthering the object of this resolution, also that a copy of these resolutions be spread upon the records and transmitted to the medical press of the country.

J. C. HOWE, M.D., Sec'y.

Chicago, Feb. 6, 1891.

To the Editor:—I am of the opinion that there is no good reason for moving THE JOURNAL office. I think Chicago is the most suitable place for it. I vote for it to remain in Chicago, for that to be its permanent home.

H. H. DARR, M.D.

Caldwell, Texas, Jan. 30, 1891.

To the Editor:—I prefer to see THE JOURNAL continue its publication in Chicago. Besides the superior facilities of communication with all parts of the country, the ambition to excel all competing cities in laudable enterprises that give prosperity to a city, which prevails there, may sharpen editorial energy to make it the best medical journal in the world.

WM. LOMAX, M.D.

Marion, Ind., Feb. 2, 1891.

To the Editor:—I prefer Chicago as the location and home of our journal for one good reason, in addition to the many others already stated by numerous correspondents, I believe the Eastern members of our profession are tainted with heretical opinions as to the propriety and practicality of our "Code of Medical Ethics" as a guide to the highest honor and truest success of the profession. Witness the heterodoxy through which we have only recently passed and fresh in the minds of all.

This reflection is not meant to impugn the characters of Eastern members generally—simply as a statement of a deplorable fact, as to a few in high places.

GUSTAVUS S. FRANKLIN, A.M., M.D.

Chillicothe, O., Feb. 3, 1891.

To the Editor:—Though living in the East and wishing it to prosper; yet I wish to be understood as advocating Chicago as the place for THE JOURNAL. 1. Because of its central location. 2. Because it is a great medical centre. 3. Because the next decade will witness it the largest city in America. 4. Because THE JOURNAL is ably edited in Chicago and is prosperous, not political nor prejudicial to sections.

C. G. CANNADAY, M.D.

23 Salem ave., Roanoke, Va., Feb. 3, 1891.

To the Editor:—I do not think the time has come, or in fact, ever will come, when our journal should be removed from Chicago. This child of our creation was born under trying circumstances, and I hope it has passed all the straits of its birth, and now at an age well on its feet, walking alone. Chicago, I believe, should be its home.

THOMAS H. BRIGGS, M.D.

Battle Creek, Mich., Feb. 5, 1891.

To the Editor:—In the absence of any sufficient reason for changing the publication office of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION from Chicago to Washington, I wish to record my vote in favor of its present location.

J. W. FERGUSON, M.D.

Canaan, O., Feb. 7, 1891.

To the Editor:—I am greatly surprised at the letter of Dr. Solis-Cohen in THE JOURNAL of January 31. I admit that THE JOURNAL has not reached the standard of excellence which the profession have a right to expect. I am, however, satisfied that "sectional prejudice" and personal ambition in Philadelphia, New York and Washington, have had not a little to do with this lowering of the standard. Dr. Solis-Cohen makes the assertion that the removal to Washington would overcome all the present difficulties.

Washington is not, and cannot be a centre for this country. Even the political conventions are not held there, and the only thing that preserves it as the National Capital is the amount of money expended in permanent government improvements.

Perhaps THE JOURNAL would not in Washington be debased to a "local" organ, but what assurance would we have that it would not be practically debased to the uses of some one service of the government. For example: With the official organ of the profession under control how easily might a Marine-Hospital surgeon annihilate a National Board of Health. For one I prefer a "local" medical journal to the tool of a political ring.

I am opposed to removal of THE JOURNAL:

1. Because such removal of plant would be expensive.
2. Because such removal would result in loss of advertising patronage.
3. Because there is not the slightest assurance that such removal would improve the personnel of the editorial board.
4. Because such removal would not increase facilities for good work.
5. Because such removal would cause loss of subscribers.
6. Because such removal would make THE JOURNAL a local journal, out of sympathy with the profession of the country.

The East has three good medical weeklies, the *Medical News*, the *New York Medical Journal*, and the *Medical Record*. The West has none. The removal of THE JOURNAL to Washington would immediately result in the establishment of a high grade Chicago weekly, which would largely decrease the advertising and subscription patronage of THE JOURNAL.

Permit me to suggest that THE JOURNAL would be more improved by having an editor for each Section of the Association, than by its removal. These sectional editors should take turn in getting out successive numbers of THE JOURNAL, under the supervision of the Editor-in-Chief, until the work of the meeting is finished, and thereafter these sectional editors should have supervision of papers in their special departments. If, for example, at a sectional meeting there are five papers read on peritonitis, publish them together, followed by discussion, as is done in the *British Medical Journal*.

HENRY B. HEMENWAY, M.D.

Evanston, Ill., Feb. 9, 1891.

To the Editor:—I am profoundly opposed to the removal of THE JOURNAL. Chicago is central and has talent to edit the same as well as Washington, Boston or New York.

A. G. PORTER, M.D.

Lebanon, Ind., Feb. 9, 1891.

To the Editor:—As a member of the A. M. A. I am decidedly opposed to the removal of THE JOURNAL to Washington, or to any other point at present. I am also opposed to locating our annual meeting at any one point. By all means let the Association remain National in character, and let it itinerate, gathering new members from all parts of our country. To permanently locate the annual meeting somewhere in the East or South, would be practically inviting our brethren on the Pacific slope to withdraw, which they would probably do.

I vote to let THE JOURNAL remain in Chicago until after the Columbian exposition at least, and let special inducements be offered all visiting physicians in good standing to visit the editor and subscribe for THE JOURNAL.

I have no fault to find with the present, or past, management of THE JOURNAL.

C. N. UDELL, M.D.

Blakesburg, Iowa, Feb. 9, 1891.

To the Editor:—The fact that Washington City, with all her macroscopic advantages, has never produced a medical journal "National" either in character or reputation, is the very reason why she is just the place which can do it. Every process attending the production of a journal, composing, printing, sewing, etc., is directly

the result of bacterial action on the part of germs which are indigenous to certain topographical and other trades unions. Likewise towns are permeated and dominated by microorganisms which determine the character of their habitat—e. g., Chicago money is infested by microbes which stimulate commercial activity, while the New York microbe inhibits the building of monuments, etc. The patent fact that for seven and one-half years THE JOURNAL has succeeded measurably in Chicago is the very reason why it cannot succeed there; because the entire environment is now reeking with these ptomaines produced by these provincial and "wild and woolly" microbes, the alkaloidal intoxicants, resulting from past editorial and business management, as it were, and even though the Trustees may succeed, that success is only clinical, and flies directly in the face of all scientific prognosis.

This may not be perfectly clear to some, but remember, Mr. Editor, this is a contribution to current bacteriology and must be made to harmonize with all past contradictory investigations as well as to anticipate all future discoveries. No man knows what discovery he may desire to claim before another moon wanes. Now, Washington City is aseptic, is free from Nationalmedicaljournalism, and if a brain new publication plant—sterilized—be set up in properly disinfected quarters, and the management be inoculated with a lymph derived from only the worst features of the most provincial medical journals until they cease to show reaction under the treatment, I think success would be assured. I fear but one thing: infection by the pathogenic germ of the *Congressional Globe*. Doubtless some such idea as this actuated Dr. S. Solis-Cohen, for he certainly would not be guilty of an *ad captandum* argument.

Seriously, but two considerations should weigh in answering the question of removal: the success, financial and otherwise, of THE JOURNAL, and the preference of a majority of its owners.

In their report made at the Nashville meeting the Publication Board, composed of nine eminent gentlemen representing the country from Maine to Arkansas, and including Washington City, stated that although they "have at different times invited competitive bids for its publication in other cities, but always with this uniform result, that it can be issued cheaper in Chicago than elsewhere."—THE JOURNAL, Vol. xiv, page 799.

Again, an editorial note in THE JOURNAL, Vol. xvi, page 204, states that of the total income of THE JOURNAL from all sources in the entire United States, "one-seventh of that amount comes from Chicago alone." A comparison between the two cities in this respect would be unjust to both places. Probably in no other city could THE JOURNAL attain the relative business success it has in Chicago, because of competition already occupying the field elsewhere.

The claim that leader writing cannot be done as well and as easily under one set of circumstances as under the other does not deserve serious consideration. European exchanges reach Chicago less than eighteen hours later than their arrival at Washington.

Personally, I would like to see more clinical matter printed; more abstracts from foreign periodicals, and this work can be printed as well one place as another, while Chicago certainly offers a fine field for an active clinical reporter.

As long as it represents a volume of Transactions THE JOURNAL will have unsatisfactory features. Just as the Quakers often suffer because of a mistaken "concern" on the part of some self-called "speaker," so will the Association listen to papers which might have been burned without irreparable loss to the profession, and THE JOURNAL must print a certain proportion of such. Change of publication office will not cure this evil.

Who own THE JOURNAL, and who should vote on a proposition to remove it farther east? Divide the country by giving Washington all the Eastern States and the

Southern States as far West as the Mississippi and let us study the matter statistically. In the List of Permanent Members, published in No. 26 of Vol. xv, I take at random first column on pages 929, 930, and 931, and test some peculiarity in the alphabetical arrangement, the first column on page 930, making a total of 300 names. With these as a basis for an estimate I find that of the total present membership of the Association, 12 per cent. are men from the Eastern and Southern States who were in the Association when THE JOURNAL was started, while of Western men whose admission antedates that time, there are 18½ per cent. The West certainly assisted at the *accouchement*. Of the total membership, 21¼ per cent. of Eastern and Southern men have joined since THE JOURNAL'S birth, while during the same time 48½ per cent. of Western men have come in. Total Eastern and Southern members 33¼ per cent., of Western members 66½ per cent. Of contributors to Vol. xv, from the two sections of country, there were respectively 66 and 78. Whether it be regarded as a local or a National publication, THE JOURNAL may properly be regarded as the organ of an Association which is largely tributary to Chicago, and no change can justly be made on a vote taken at Washington in May. Let us have the postal card vote by all means.

CHAS. A. HOUGH, M.D.

Lebanon, Ohio, Feb. 7, 1891.

To the Editor:—Now that the question of changing the location of THE JOURNAL is under consideration, it is important that no time be lost in plainly laying before our readers and members the reasons why its removal should be demanded, and there is no place or no medium through which the matter can be better, fairer or more fully considered, than in that weekly, which is the property of us all; for it may as well be generally known that this transference of location cannot be consummated *except through specious, delusive argument, wily manipulating and shrewd diplomacy, with the aid of sharp parliamentary tactics*; in other words, by a genuine *coup d'état*. Our membership is bound by no alliances, can afford to act independently, and must be prepared to meet and neutralize by a compact and concentrated majority.

So far I have not seen a *single valid reason* why we should move East; on the other hand, the indications point the other way; that if another location is selected, it must be in the direction of the Occident, for the bone and muscle—so to speak—and the brain, too, of the American Medical Association, come from the West.

True, we have at the present time greater literary centres east of the Alleghenies; more books and professors. So with the "late unpleasantness"—the South had the generals and the gentlemen, but the North had the men and money.

To-day, the West has the natural wealth, with an enormous and rapidly multiplying population, and the time has now arrived, in medicine as in politics, when the voice of that section must be respected in our councils.

It has been intimated that ours is a sort of a third-rate journal; indifferently edited and behind the times. Now, the contrary is incontestably the fact. Subscribing for nearly all our leading medical weeklies, there is not one which I read with greater relish and profit than THE JOURNAL. What should particularly commend it to us, is that it is *out and out American*. Its pages are not stuffed and padded with abstracts from other exchanges, which have often nothing to justify their appearance, except because they "are foreign, you know."

The pages of our journal are open to the best American thought, to the humble plodder, as well as to the more pretentious professor. Its present status is one of prosperity, its future, conducted on the same lines, is unquestionably one of unparalleled success.

Let us, then, *stand together, regardless of section, and*

insist on no removal from Chicago; a city for its size and importance, the most centrally located and accessible in the United States.

Let those satisfied with the present *régime*, and its publishing centre, MOVE EARLY, and see to it that their friends are in their places at the next meeting of the Association in Washington, D. C., to maintain their position and cast their ballots.

THOMAS H. MANLEY, M.D.

New York, February 9, 1891.

ASSOCIATION NEWS.

American Medical Association.

The forty-second annual session will be held in Washington, D. C., on Tuesday, Wednesday, Thursday and Friday, May 5, 6, 7 and 8, commencing on Tuesday at 11 A.M.

"The delegates shall receive their appointment from permanently organized State Medical Societies, and such County and District Medical Societies as are recognized by representation in their respective State Societies, and from the Medical Department of the Army and Navy, and the Marine-Hospital Service of the United States.

"Each State, County, and District Medical Society entitled to representation shall have the privilege of sending to the Association one delegate for every ten of its regular resident members, and one for every additional fraction of more than half that number: *Provided*, however, that the number of delegates for any particular State, territory, county, city, or town shall not exceed the ratio of one in ten of the resident physicians who may have signed the Code of Ethics of the Association."

Members by Application.—Members by Application shall consist of such Members of the State, County, and District Medical Societies entitled to representation in this Association as shall make application in writing to the Treasurer, and accompany said application with a certificate of good standing, signed by the President and Secretary of the Society of which they are members, and the amount of the annual membership fee, five dollars. They shall have their names upon the roll, and have all the rights and privileges accorded to *permanent members*, and shall retain their membership upon the same terms.

The following resolution was adopted at the session of 1888:

That in future each delegate or permanent member shall, when he registers, also record the name of the Section, if any, that he will attend, and in which he will cast his vote for Section officers.

Secretaries of Medical Societies, as above designated, are earnestly requested to forward, *at once*, lists of their delegates.

Also, that the Permanent Secretary may be enabled to erase from the roll the names of those who have forfeited their membership, the

Secretaries are, by special resolution, requested to send him, annually, a corrected list of the membership of their respective societies.

AMENDMENTS TO THE BY-LAWS.

Offered by Dr. A. L. Gihon, United States Navy:

That the first day of the meeting of this Association shall be the first Wednesday of May or June respectively, instead of Tuesday.

By Dr. N. C. Scott, Ohio:

That the Committee on State Medicine be abolished, inasmuch as the Section on State Medicine occupies the entire ground.

By Dr. E. A. Wood, Penn.:

That the word Physiology be stricken from Section*1, and a new Section, entitled the Section on Dietetics and Physiology, be formed.

By Dr. J. C. Culbertson, Ohio:

That the State and Geographical District Societies in affiliation at this time with this Association, having a membership of 100 or more, shall be recognized as branches of the American Medical Association.

That all members of said Societies enjoy all the rights and privileges now accorded to delegates.

By Dr. Wm. H. Daly, Penn.:

That in future the permanent members have all the rights of delegates.

ADDRESSES.

On General Medicine, by Dr. E. L. Shurly, Detroit, Mich.

On General Surgery, by Dr. Jos. M. Mathews, Louisville, Ky.

On State Medicine, by Dr. W. L. Schenck, Topeka, Kan.

Committee on Arrangements: Dr. D. C. Patterson, Chairman, 919 I street, N. W., Washington, D. C.

WILLIAM B. ATKINSON, M.D.
Permanent Secretary.

BOOK REVIEWS.

PRINCIPLES OF SURGERY. By N. SENN, M.D., Ph.D., Milwaukee, Wis. Illustrated with 109 wood engravings. Philadelphia and London: F. A. Davis, publisher. 1890.

Principles of surgery, surgical pathology and general surgery are synonymous terms. This is the soul, the brain, of the science of surgery. It is the red thread that runs through the surgeon's every action, and leads and guides him in diagnosis, in prognosis, and in treatment as well. It lays down broad general laws and truths, which are the same everywhere, in any number of details of a given case.

Special surgery is a conglomerate mass of details, of anatomy, technique of operating and varied forms of special diseases in special regions, it is impossible for any surgeon to remember and know by heart all of these at one time. Thus,

he has his books in which to find the detailed description of a disease or operation when he meets a case requiring this special knowledge.

General surgery, on the other hand,—the broad general laws of Nature,—the student, the practitioner, the surgeon, must have ever present in his memory. It must be a part of his every-day thought and reasoning. He must know the general laws by heart, because he has to use them in his every-day work. The principles of surgery is the most important part of the science of surgery.

Since the appearance of Billroth's "Surgical Pathology," twenty years ago, no book has appeared covering this special field.

Too little space is devoted to general surgery in the modern textbooks, Tillmanns, Fischer and others. Koenig's otherwise excellent work is too old as regards this branch of the subject, excepting Part II, published in 1889, written by Riedel, which is most excellent and entirely modern, but which covers only part of the field. Besides this, Koenig's Surgery is not as yet translated into English.

In the last twenty years general surgery has been revolutionized by the development of bacteriology and Lister's antiseptic method. Bacteriology has revolutionized pathology, which is now written in an entirely new language, incomprehensible to the readers of twenty years ago. New editions of Billroth's work have entirely failed to bring it up to date. The Lister method has revolutionized treatment just as much. Thus, the views of treatment even of as apparently simple an affection as a furuncle or felon have changed entirely, and so much the more in graver affections. The advice given in the general surgery of to-day is in many respects diametrically opposed to the advice of twenty years ago, and many a procedure, which at that time seemed hazardous or aggressive, is to-day not only legally permissible, but imperative, is the rational treatment, and adherence to the old conventional methods must be considered as neglect, and even as malpractice.

In the first chapter, on regeneration, the author draws a sharp line between this process and inflammation, defining regeneration as a formative process in contra-distinction to inflammation, a destructive one. In this chapter he takes strongly the ground of homology in cell development as opposed to the metaplasia of Virchow. I think this point is well taken in a text-book for students, in which it is important to have as distinct landmarks as possible, in order to facilitate comprehension.

The results of modern investigation in such processes as karyokinesis, vascularization, cicatrization and epidermization, are fully described, and lead to a number of practical remarks on the aseptic and antiseptic treatment of wounds, which are most important for the surgery of to-day.

In the chapters on blood-vessels and fractures,

the author speaks with the authority of an original investigator.

In the chapter on inflammation, the author holds that inflammation is always caused by one or more kinds of microbes, thus entering another field, where the previous valuable writings of the author make him perfectly at home. A careful consideration of the modern histology of all the tissues concerned in inflammation makes this chapter most important and interesting. The modern field of phagocytosis is ably considered, and the author believes that there is positive evidence of the potency of this process in limiting or combating infective invasions.

Chronic inflammation, the granulomata of old, which is always due to the action of specific microbes, is ably discussed in its various forms, and a comprehensive light shed upon the variety of course and symptoms, by a careful consideration of the mixed infectious as the cause of abscess formation in these diseases. By inserting practical points in diagnosis and treatment where modern research has made it possible, this otherwise rather dry and uninteresting subject has been made much easier for the student, and very attractive.

In the chapter on the treatment of inflammation, the author is entirely modern, and does away, it is hoped for all time, with the legion of cataplasms and counter-irritants of times gone by, as well as with a number of useless drugs, which must give place to the healthy stimulants. Among these otherwise very critical considerations, I am surprised to find the author's unexpected faith in cold applications.

The important subject of pathogenic bacteria has received an exhaustive consideration, as would be expected from the author of the most complete monograph on surgical bacteriology, which, as it well deserves, has been already translated into several languages. The chapter is short, clear, and is not burdened by details. This is a difficult task, on account of the mass of literature now existing, and evidences just criticism in an author conversant with the whole literature of the subject.

The subject of necrosis in all its pathological and clinical varieties, is entirely modern, and has been made an exceedingly valuable chapter to the practitioner by elaborately detailed practical advice, given from cases of every-day occurrence. The descriptions are made such life-like pictures of cases that we meet with that any practitioner will recognize them when he reads them, and they will constitute for him a valuable guide in diagnosis and treatment, such as I have not yet found in any of the text-books on general surgery.

The subject of suppuration is probably the most important chapter in modern surgery. We find in this book a clear exposé of the intricate connection between the different forms of sepsis

and the different microbes, with their relations to etiology, clinical symptoms, and treatment. The landmarks in history also receive due consideration. The detailed advice for the treatment of each individual form, from the small localized felon up to the acute, rapidly progressing fatal sepsis, is exceedingly important to the practitioner.

In the chapter on osteo-myelitis, the author himself has made a valuable addition to the progress in modern treatment in the filling of bone cavities by antiseptic decalcified bone chips.

The chapter on intra-cranial suppuration is exceedingly interesting and practical, clear in differential diagnosis, exhaustive in advice, and founded on the manifold researches and observations in this modern field of surgery.

The author follows suppurative inflammations through all the tissues of the body, giving for each territory the results of modern research as to etiology and the modern operative methods as well.

The important subjects of septicæmia, pyæmia, and septico-pyæmia, almost incomprehensible as they are in all other works up to date, can be read in this work with great interest, as the author has been especially fortunate in drawing comprehensive lines and pointing out landmarks founded on modern investigation and leading to advice, also entirely modern, in the war against these diseases, which are, we might say, the most formidable enemies of the surgeon.

The chapter on surgical tuberculosis belongs exclusively to modern surgery. The rapid strides forward of the last one or two decades have revolutionized the diagnosis and treatment of this extensive field of surgery, which includes, we may say, the greatest number of every-day cases for operation. With the exception of Koenig and Riedel, who are not accessible to English readers, we find in this work the first exhaustive and comprehensive description of surgical tuberculosis, in all its varied forms and treatment. This is eminently practical also in this book, as the examples cited of tuberculosis of joints, glands, etc., are the typical ones of every day surgery, and the operative treatment, as described, is so clear and exhaustive, that it is a safe guide for any operator.

The little chapter on fascial tuberculosis is entirely new, and is based on original observations of the author, which, so far as I know, have not before been published.

In a review it is impossible to do more than to point out here and there what strikes the reader most markedly. Thus, a multitude of subjects can receive no mention. In general, I will say that each subject has been discussed exhaustively. If we take at random one of the smaller subjects, as, for instance, actinomycosis, we find, as a proof of the comprehensiveness and completeness with which the subject has been treated, each of the following points distinctly discussed: History; description of microbe; cultivation ex-

periments; inoculation experiments; sources of infection; pathology and morbid anatomy; clinical varieties, including cutaneous surfaces, alimentary canal, respiratory organs and brain; symptoms; diagnosis; prognosis and treatment.

As a teacher of surgery, I have for a long time felt the need of a work on general surgery short enough to be read by the student, complete enough and modern enough to bring the subject up to date. Such a work we have in the book before us. It has been written with just discrimination in the selection of the grains of gold in the enormous mass of the modern literature of the subject.

It is an important aid to the teacher, enabling him to do away with the tedious, didactic lecture, and the plowing through the enormous literature to find what the student of to day needs. I, for one, intend to use the book as a text-book for the students to learn, using the lecture hour for quizzing and demonstrations, supplemented by remarks on matters of interest in the current literature of the subject.

To the practitioner and surgeon this work brings the subject of modern surgery up to date, in a comprehensive form, and he will find it a valuable and safe guide in his everyday work in diagnosis, prognosis and treatment.

The illustrations are numerous, well chosen and well executed, and the publisher deserves credit for the appearance of the work.

CHR. FENGER.

MISCELLANY.

Official List of Changes in the Stations and Duties of Officers Serving in the Medical Department, U. S. Army, from January 18, 1891, to January 21, 1891.

Major William H. Gardner, Surgeon, is relieved from further duty in the field, and will return to his proper station. By direction of the Secretary of War. Par. 2, S. O. 19, A. G. O., Washington, January 23, 1891.

Major Stevens G. Cowdrey, Surgeon, extension of leave of absence on account of sickness granted in S. O. 302, December 27, 1890, from this office, is still further extended two months, on surgeon's certificate of disability. By direction of the Secretary of War. Par. 13, S. O. 19, A. G. O., Washington, January 23, 1891.

Capt. Walter Reed, Asst. Surgeon, is relieved from temporary duty at Ft. Keogh, Mont., to take effect as soon as his services can be spared by the commanding officer of that post, and will then return to Baltimore, Md., and resume his duties in that city as attending surgeon and examiner of recruits. By direction of the Secretary of War. Par. 3, S. O. 20, A. G. O., Washington, January 24, 1891.

Capt. William C. Owen, Jr., Asst. Surgeon, is relieved from temporary duty with troops in the field, to take effect as soon as his services can be spared, and will then return to Muskogee, Ind. Ter., and resume his leave of absence. By direction of the Secretary of War. Par. 3, S. O. 20, A. G. O., Washington, January 24, 1891.

Capt. Charles M. Gandy, Asst. Surgeon, is relieved from temporary duty in the field, to take effect when his services can be spared by the commanding officer of the troops with which he is serving, and will then return to Ocean View, Cape May Co., N. J., and resume his leave of absence. By direction of the Secretary of War. Par. 1, S. O. 21, A. G. O., Washington, January 26, 1891.

Capt. Robert J. Gibson, Asst. Surgeon, is relieved from further temporary duty in the field, to take effect as soon as his services can be spared by the officer commanding the troops with which he is serving, and will then return to New Haven, Conn., and resume his leave of absence. By direction of the Secretary of War. Par. 6, S. O. 22, A. G. O., Washington, January 27, 1891.

Capt. William Stephenson, Asst. Surgeon, will proceed without delay from Columbus Bks., O., to Ft. Wayne, Mich., and report in person to the commanding officer of that post for temporary duty, and upon completion of the same will return to his proper station. By direction of the Secretary of War. Par. 13, S. O. 23, A. G. O., Washington, January 28, 1891.

LECTURES.

PATHOLOGY OF PHTHISIS PULMONALIS.

A Lecture delivered at the Post-Graduate Medical School of Chicago, January 25, 1891.

BY HENEAGE GIBBES, M.D.,

PROFESSOR OF PATHOLOGY, UNIVERSITY OF MICHIGAN.

Mr. President, Ladies and Gentlemen:—I must first say that when I left home last evening I was not aware of what was before me; I have not come prepared to make a set speech this evening, and if you find what I say rather disconnected, I hope you will excuse me.

What I want to say in connection with this subject is on the part of the pathology and etiology of the disease, and how we have arrived at the place we now are, in which we consider we have done something towards curing the disease called consumption; I use the word consumption in the generic sense as applied to those diseases that are found associated with consolidation and decay of the lungs, together with wasting and emaciation of the body. We know that in making a post-mortem examination of a case of disease of the lungs we find a variety of changes there, appearances indicating in some cases that the disease has not progressed very far, while in others we find large consolidations, and in some parts large cavities caused by breaking down of this consolidation. So far we have only seen, with the naked eye, one appearance which is constant, and that is consolidation. Now if we stop there, at the naked eye appearance, we have simply one form of disease, consolidation of the lung with breaking down afterwards and formation of cavities; but when we bring in the aid of the microscope, and prepare sections cut from the lungs, we find a totally different state of things. I think this is one of the most important problems that we have before us at the present time, that is to say, whether we are to believe in the unity or duality of this disease. We know that the unity of this disease has been taught by a large number of men who fully believed in it, but I have been working on this subject for a number of years, and I simply cannot satisfy myself that it is so. I would point out that if you

take those cases where there is consolidation of the lungs, and carefully harden those lungs, cut sections from them, stain and prepare them for the microscope, and examine them, you will find that they divide themselves into two kinds. You will find that the one is inflammatory, and the other a new growth in the lungs, which is tubercle. I have taken these photographs from cases of acute miliary tuberculosis, in which you can see the process in the early stage, and I think they will show you the distinction. It seems to me that at the present time it is an important question as to whether there are two distinct diseases or not. You are aware that some dogmatic writers have insisted upon the unity of phthisis, but I have no hesitation in saying, from a careful study of diseases of the lungs, that this is not the case. There are two distinct forms of disease in the lungs, one the inflammatory breaking down, the other a new growth. I would therefore as a basis, divide lung diseases into two kinds, the inflammatory and the tubercular. And I would then, as a kind of sub class to these, add acute miliary tuberculosis, which must be distinguished from these because its symptoms are so different; it does not run a long course. It never causes ulceration into the respiratory passages, and in cases of acute miliary tuberculosis you never get bacilli in the sputum, therefore I would make a sub-class of this. Take the inflammatory form of phthisis; we all know the form of pulmonic phthisis where you have in the first place a catarrhal pneumonia, there may be bronchitis, and extension of that into the lungs and an inflammatory condition of the lungs which ends in consolidation there. This consolidation may clear up and leave the lungs as whole as they were before, provided the damage done by the inflammatory process has not been so great as to destroy the vitality of that part of the lungs affected; but if, on the other hand, consolidation has gone on and the flow of blood through the parts has been arrested by the inflammatory process, and the damage to the lung is so great that a part of it is destroyed, that is dead, we then have retrograde changes resulting in what we call caseation. There is then the inflammatory form; this, if carried out to the destruction of the parts, ends in caseation and liquefaction,

which ejected through the bronchi leaves a cavity in the lung. That seems to me perfectly clear; I think that is the experience of all of us.

In the case of tuberculosis we have a totally different thing, we have there the formation of tubercles. Now I must explain what I mean by tubercles. It is a new growth in the lungs composed of a fibroid tissue; I call it fibroid tissue because I am not clear that it is fibrous tissue. The reaction is exactly the same as that found in fibrous tissue; it is distinctly a new formation in the lungs, and it is not of an inflammatory character, it contains one or more giant cells. This is distinctly a new formation; in a well-stained specimen it looks something like an elastic tissue, but I do not think it is ordinary fibrous tissue. There is this peculiarity in regard to tuberculosis, you do not get a large tubercle, when you first see the consolidation it is not one single tubercle, but an aggregation of small tubercles. A tuberculosis grows in the lungs by beginning as one or two small ones together, which gradually increase in size, and numerous smaller ones are formed around the edges, so you get a large mass which looks like a consolidated form of pneumonic phthisis. This tissue is peculiar, it has this characteristic that it readily breaks down, and for this reason it has been included in the infective class, together with the lesions of syphilis. Now we know there is a kind of tissue formed in syphilis which varies very much, but still it is a new growth, and we know that under certain drugs this can be changed and destroyed and broken down, leaving nothing behind but destroyed tissue. In tuberculosis we also have a new tissue, but of a more stable character. We know that in small tubercles, after they have grown to a certain size, the centre indicates the beginning of necrosis, and on the outside we have the reticular tissue containing the giant cell. The next stage is that the whole or a part begins to break down, and then it passes into what we call caseation, because we do not know any better name. The chemists, who ought to be able to support us in this, never do so; we have not yet had the composition of caseous matter worked out. What I want to know is whether the caseation in phthisis is the same as that of the breaking down of tuberculosis. If that was shown we would have more data to go on in forming an idea of the disease than at present. In these two forms we have consolidation as one cause of inflammation, and in the other a new growth, both resulting in breaking down and the formation of what we may call caseation. The result of these two diseases is the same, that is to say, formation of cavities in the lungs, while the beginning is totally different.

Before I speak of the formation of tubercles in the lungs I would pass on to acute miliary

tuberculosis. Every case of acute miliary tuberculosis that I have been able to get during the last nine years I have examined carefully, and have found always the same results. I have had to place them in two classes, the inflammatory and the tubercular. So we have acute miliary tuberculosis differing so much from either chronic phthisis or the more chronic form of pulmonary disease, still being the same clinically; it is almost impossible at present to discriminate between the two forms of acute miliary tuberculosis. In post-mortem examination of the lungs you cannot tell them apart, yet when we study these small nodules in the lungs we find two kinds, the inflammatory and the tubercular, and in this condition we can study them perfectly. But this is the difficulty we have to contend with in studying the disease and the lesions produced by that disease; we cannot get at the initiation of the disease in the ordinary forms, but we can in acute mil-

FIG. 1.—Typical reticular tubercle (essential type of tuberculosis, Payne). Fibroid tissue, giant cells, necrosed centre. From a case of pulmonary tuberculosis where all the lesions were of this structure, and no tubercle bacilli could be found.

iary tuberculosis. Figs. 1 and 2 are photographs of cases of children that died of acute miliary tuberculosis. The disease lasted about the same time, and the children were of the same age, the physical signs and symptoms were alike and were diagnosed as miliary tuberculosis. As far as I have gone, and I am certainly within bounds in saying that I have cut over a thousand sections of these lungs, and stained and examined them, I have never found any section made from either one of these lungs that did not absolutely put itself into one class or the other, inflammatory or tuberculous. So also in the more chronic form the division is absolute between the two, you

may divide the disease absolutely into two classes, tubercular and inflammatory.

With regard to the tubercle, I may say this: It has been said that the reason why there is this difference of opinion between some observers is that some take one form of tubercle and some another, on which to form their basis as to what a tubercle is. That is utterly wrong; you may make fifty or one hundred or more sections of the lungs in cases of acute miliary tuberculosis of the tubercular kind, and you will never find two that are exactly alike. There is always this sharp difference between the two forms: you have on one side an inflammatory process, with no attempt at structural formation; in the other there is a reticular structure, a new growth. Now, coming to the initiation of these two, and finding that the earliest stages in their growth, and finding that these two begin in the one form inflammatory

highly magnified specimen, showing the tubercular structure, with large giant cells in it.

Now in regard to the etiology of these two diseases: it seems to me that there ought to be no difficulty in working out the etiology of the inflammatory form of phthisis: it begins in inflammation and ends in the ordinary way; it simply breaks down. But the tendency is to consider what was formerly called causative as now only predisposition, that leads one only into difficulty, because now we have to face the question of the relationship of the tubercle bacillus to this process. Coming to the earliest stage of the disease as shown in these two photographs, we are told by many observers of the present time, that the tubercle bacillus is the virus of the disease. That phthisis pulmonalis and tuberculosis are really the same disease: that wherever the tubercle bacillus is found, there is tuberculosis. Therefore, if we want to find the starting point, we must examine the earliest stage of the disease; but when we look at the very commencement of these two forms and look for the tubercle bacillus—what is the result? We cannot find it. I can say that in all the cases I have examined I have never been able to find the tubercle bacillus at the commencement of the process in the human lung. I have carefully picked out from the earliest cases what seemed to be representative ones, and photographed them, so that you can see what is there. This is the commencement of the disease, and the virus of the disease, the thing which starts it, is absent. There is another little difficulty in connection with it; that is, in these two forms in acute miliary tuberculosis you will never find the tubercle bacilli in the sputum. But you will never examine one of the inflammatory type of that disease without finding in the centre of the inflammatory mass a large number of tubercle bacilli. Hamilton has described this peculiar form very well; he calls it "disseminated catarrhal pneumonia," and he says that not a few cases recover from this. He says that in this form you will find no trace of tubercular formation, no organization, no structure whatever. That agrees exactly with what I call the inflammatory form of acute miliary tuberculosis, and you will see in these specimens that the centre of the inflammatory mass contains a large number of tubercle bacilli. In the tubercular form I have examined many cases where there were no tubercle bacilli at all to be found, not only at the commencement of the disease, but all the way through it. There were none to be found in many hundred sections I had made of that condition; and others have put it on record that they had been unable to find them. Further than that, I have had cases of tuberculosis in the more chronic form, where the disease existed for a long time, under observation, and where there were no bacilli in the sputum; where the post-mortem examination showed large

FIG. 2.—Caseous tubercle in lung of child in case of acute miliary tuberculosis so-called. Centre of mass contains a large number of tubercle bacilli.

from the commencement, and in the other reticular, we are justified in deciding that these must be two distinct diseases, this the inflammatory condition, and that the tubercular. (Figs. 3 and 4.) This photograph shows that the commencement of the one is reticular from the beginning; you may see where a small tubercle is commencing, and you see this is formed from a new growth, and that is to be found in the very commencement; while the other is nothing but a collection of inflammatory cells. I have said enough to show that these are two diseases.

Unfortunately, I am not on the fashionable side, and what I have done on this subject is ignored; but I think we have come to a time when we cannot afford to ignore this. This is a more

cavities in the lungs, and sections of the lungs showed large tubercle breaking down and forming cavities, but without one single bacillus in them. So if the tubercle bacillus is the virus of the disease, as far as I can see, it is absent from the commencement of the process in both forms; and even absent throughout the whole course of the disease in some of these forms of tuberculosis.

The next thing which is supposed to show the tubercle bacillus in its position, is the effect when inoculated in animals. It has been stated positively, and on this is founded a great deal of what has been laid down dogmatically, that the lesion produced by inoculating tubercular material is identical with the small tubercle you find in the lungs; that is to say, it is a growth of fibroid tissue containing giant cells. I must disagree entirely with this. I have never seen in

the inoculated animal; that is to say, the new condition is inflammatory, and goes on to breaking down. These are photographs of the lung of a monkey inoculated with pulmonary phthisis; there the change is exactly what you find in the inflammatory form of acute miliary tuberculosis; that is to say, there is no effect on the connective tissues of the lung, there is no attempt at new formation, and if this is the case it is a very important thing, because, on the other hand, inoculation with tubercular material has produced in the lung of a monkey an entirely new condition. This photograph is taken from the spleen, where the monkey was killed eleven days after the inoculation, and in the centre of the Malpighian corpuscle of the spleen is seen a mass of large cells, which are exactly similar to those found in a strumous cervical gland. You know in the

FIG. 3.—Inflammatory tubercle commencing. Lung of child Case diagnosed as acute miliary tuberculosis. Lung injected with Berlin blue.

FIG. 4.—Reticular tubercle commencing, from a case of acute miliary tuberculosis.

the lung of inoculated animals a true tubercle, that is to say, the reticular formation with giant cells, such as you will find in acute miliary tuberculosis of the tubercular form, and which, Payne says, is the essential type of the disease, and what we have always been taught to believe a tubercle. This fibroid tissue with giant cells you will not find in inoculated animals, therefore the disease does not reproduce itself in animals. I have been doing work lately in studying the changes produced by inoculation, where I could prove that the inoculating material was taken from pulmonary phthisis and pulmonary tuberculosis, and although I cannot speak positively, I believe that the result produced by inoculation of caseous products from pulmonary phthisis produces a condition similar to that in the lung of

strumous cervical gland, which is one of the lymphatic glands, you have a number of masses of adenoid tissue, and between this physiological mass and capsule there is a lymph space forming a sinus there, the effect of the disease on one of these glands alters it entirely by the formation of these large cells, and the lymphatic tissue is entirely changed into masses of large cells with a number of giant cells in them with, after a time, caseation and breaking down in parts, which ends so often in suppuration. Now the effect produced in the monkey's spleen by the inoculation of tubercular matter has been to produce the formation of cells very similar to those found in struma or scrofula, there is certainly a strong resemblance, but as I have said, I have not had sufficient data as yet to speak positively on this. However, I

am endeavoring to carry out the investigation, but I have to take the sputum from cases and inoculate guinea pigs, and trust to providence to give me a post-mortem, and I can't get one post-mortem in twenty, so I am wasting guinea pigs. But I would like to give you the idea, because it seems to me there must be something in this condition, but whether it will be ultimately proved that there is any connection between scrofula and this tubercular inoculation I can't say as yet.

The next point is as to the relation of the tubercle bacillus to the disease, and the proof of inoculation by pure culture of it in the production of tuberculosis. I don't think those who have worked in this have given any statements whatever as to what the products were; we have had the bald statement that histologically the lesion produced by inoculation was identical with that found in the lungs. And this has been stated by men who knew nothing whatever about normal histology. I have met it so often that I feel convinced that such is the case, and I think it is materially hindering our investigations, especially in diseases of the lungs.

One other point I would like to mention is the consolidation produced in the lungs by other diseases. I have spoken so far of catarrhal pneumonia, caseation and the new formation tubercle, and then of the minor class of acute miliary tuberculosis which divides itself into two forms. But there are other conditions, lesions of syphilis and hydatids which sometimes are included in consolidations of the lungs. And another one is croupous pneumonia; we certainly sometimes get a consolidation produced by acute pneumonia remaining in the lung. While it remains in the lung as a solid mass it does not do much harm and gradually dries up, but it seems that some change will take place which produces an irritating action around the edge of the consolidated mass, and this may be either acute or chronic. If chronic, it does what chronic inflammatory action always does throughout the body, causes an increase in the fibrous tissue, and we know what the result is; we have the formation of fibrous bands of tissue in the lung caused by the chronic inflammatory action. But on the other hand, there may be an acute inflammatory process set up which results in the liquefaction of more or less of this consolidation, with the formation of a cavity from that, and here we have another way by which cavities are formed in the lung, and it certainly has no intimate relation with either inflammatory or acute tuberculosis. In regard to the clearing up of these different lesions in the lungs, we may, instead of having acute breaking down there and the formation of a cavity, have the mass dry up, and act as a chronic irritant in the lung, producing the usual chronic inflammation, with the result that it is isolated by fibrous tissue; and we have a chronic

cystic tissue in the lung which will either leave a cicatrix there or else a fibrous capsule with a mass of caseous material in the centre.

With regard to those specimens, I cannot say what the condition originally was, the mass in the center is simply caseous, and whether it was a gumma or a tubercle, I cannot say. Whatever was there is broken down and all structure is lost, but still it has produced the same effect of setting up chronic inflammatory action.

I would ask if I were going to kill the tubercles, What would become of them? Do they remain in the lungs as foreign bodies and by their irritation set up these little fibrous cysts which contract on their contents? If so, it would seem to me that the last state of that man would be worse than the first, the remaining lung tissue would be put upon the stretch so that there would be a kind of mechanical emphysema produced which he could hardly sustain.

In regard to the argument in favor of tubercle bacillus being the virus of phthisis; if you make a pure cultivation of bacilli and keep cultivating that from one tube to another, extending over a number of years even,—it will not do to go too far or they will lose their vitality—you are supposed to free them entirely from anything which may have been introduced in the first place from the organ that they were taken from, and you are supposed then to have a pure culture, and that if you inoculate an animal with this it will produce a characteristic lesion. It will produce a change in the lung of the inoculated animal; this is a rather difficult thing to get over, because that, together with the histological consideration of the introduced lesion, are the main points on which the position of the virus of tuberculosis rests. I would ask if it has been proved to demonstration that the cultivation of tubercle bacilli are absolutely pure? if nothing is carried from this mass on which they are cultivated? Has there been any attempt to prove that? That is a question which is very difficult to answer; but unless it is answered by exact science we may doubt it. We ought to consider all honest opinions, but we do not want to have opinions rammed down our throats as facts until they are proven. If this to be considered as the virus of the disease it must have its basis absolutely sure and certain before we accept it. Now take the example of the jequirity bacillus, which was found in an infusion of the beans sold in India as prayer beans. If you take an infusion of them and inoculate it into the eyes of animals you will produce an intense ophthalmia. It is used by the natives for trachoma, and produces an intense inflammation which lasts two or three days, and then all trace of the disease is gone. It has been found by investigation that after making this infusion and keeping it for two or three days, when it was examined it would be found teeming with bacilli. This bacillus was

cultivated in the same way as tubercle bacillus. Generation after generation was cultivated by a man as careful as Sattler was known to be. Klein made these cultivations and worked it out thoroughly, and I recall his saying to me, "If there is any one case in which it is proved to demonstration that the bacillus is the virus of disease it is this." He made an infusion of the bean in sterilized water, with every precaution against contamination, and inoculated the eyes of eight rabbits, and eight tubes of sterilized peptones. He examined them every day for two or three weeks and not a trace of microorganisms grew in them, but these animals got such an inflammation that they died with their heads swelled to an enormous size. He next took an infusion of jequirity bean teeming with bacilli and heated it to 100° centigrade and kept it so for a minute until the heat had destroyed all formed bacilli. He then took the spores from that and cultivated them until he grew bacilli morphologically identical with the bacillus he had before, but on inoculating the eyes of animals with it it had no effect whatever. Prof. Warden succeeded in isolating the alkaloid, not only from the beans, but the leaves, stems and root of the plant, and it was that which was doing all the mischief; it was shown beyond any doubt, in a case where it would seem to be absolutely proven that the bacillus was the virus of disease, that the bacillus had nothing to do with it.

Now I do not think we ought to take it as being absolutely true that the tubercle bacillus is the virus of the disease from the production of a lesion by an inoculation of so called pure culture, and work on that line. Dr. Shurly and I have always held the view that there is something there beyond the bacillus, and we have never troubled the bacillus except to find when it has gone out in the sputum of the patient treated. We have not worried that bacillus at all, others have been doing that. We have been working on the line that there was some morbid product there which could be combined with some chemical and rendered inert. We commenced work with that idea, and we certainly did succeed by using iodine, and we got to that stage the year before last where we could inoculate a guinea pig with tuberculosis and prevent the development of it; prevent anything developing beyond an abscess at the seat of inoculation, where we would find fluid pus full of bacilli, but with no lesions except fatty change in the liver, but which showed different conditions from ordinary fatty change, which, as you know, is generally around the periphery of the lobule. It was not necessarily confined to one lobule but sometimes running through the middle and changing into this fatty infiltration, so that when you held a section up you could pick out the patch that had undergone this change. We considered that we

were not justified in doing this to human beings and we then turned our thoughts to other subjects. Dr. Shurly worked on animals while I worked on pure cultures of tubercle bacillus, until by using a number of things we found a way in which we could render the tubercle bacilli in the cultivation absolutely inert so far as the gross lesion in the guinea pig was concerned, although it was not dead. We considered we had done this by using some chemical which would combine with the morbid product which we thought, and still think, must exist in these cultures, and that we have rendered that innocuous by forming a combination of substances. The one I found most efficacious was chloride of gold and sodium. By using chloride of gold I killed the bacilli right off. I communicated with Dr. Shurly on the results and he was struck with the idea of injecting this substance. We had before been giving insufflations of different drugs, and he thought that by injection we could introduce this fluid in such a way as to be carried to these parts where the morbid product especially existed, and that it would act in the same way. We found we were justified in that by the effect on animals, and from that we went on trying the effect on human beings.

From what I have said I think you will see I am at least justified in coming before such an assembly as this. I can assure you that it was with a great deal of trepidation that I began. I did not know whether I would be allowed to go on to the end. I have been sat down on so unmercifully on the other side that I feel considerably reduced in height in consequence. I hope you will not think I have been too dogmatic, but will pardon me when I say these conclusions are the result of careful work extending over eight or nine years. If you prove that I am wrong I hope you will let me down gently.

THE TREATMENT OF PHTHISIS.

A Lecture delivered at the Post-Graduate Medical School of Chicago, January 23, 1897.

BY E. L. SHURLY, M.D.,

PROFESSOR OF LARYNGOLOGY AND CLINICAL MEDICINE,
DETROIT, MICH.

Mr. President, Ladies and Gentlemen: I will not occupy your time very long as my colleague has gone pretty thoroughly into the explanation of our work in giving you our pathological ideas; I shall speak to you only from a clinical standpoint. It is the predominating opinion of physicians that the bacillus tuberculosis is the specific and only cause of the several forms of disease known as tuberculosis, and from its behavior it is a very hard thing to explain away. But when we consider from a clinical standpoint this bac-

terium, as the cause of the several conditions, known as tuberculosis, phthisis pulmonalis, in its several forms, tuberculous joint disease, scrofulosis, so-called tubercular skin diseases, bone disease, some forms of leprosy, besides other complex affections, it must strike any one who will think of it for a moment, as being impossible!

With regard to the bacillus, of course its specific character we do not question at all; nor its value as a diagnostic sign. The results observed are explained on the theory that it should have a nidus, and upon this nidus develop the disease, or, that it may remain latent in the body, constituting animal parasitism, a condition which was foreshadowed by Dr. Lionel Beal, twenty years ago, or that the bacillus is imbibed, exists for a time in a latent state and is then eaten up by leucocytes or by other microbes — phagocytosis. Now if the bacillus be the cause of these complex conditions we must recognize one or the other or all of these theories.

We have in phthisis pulmonalis, as you are well aware, three distinct clinical types of disease. It is almost impossible, so far as I know, to distinguish acute phthisis from miliary tuberculosis, the course is rapid in both, the temperature makes about the same range in each, about the same class of individuals are effected and present about the same symptomatology, which I will not detain you by describing. There is another form which we may properly denominate the *subacute form*, in which the patient has a distinct catarrhal inflammation, existing for a certain length of time, in the mucous membranes of the bronchial tubes, with little or no constitutional disturbance at first, but simply local disturbance, cough and respiratory sensations, while, sooner or later constitutional disturbances come on, and we find, if we make frequent observations by physical examination that the inflammation is extending to the smaller tubes, and involving the air cells; finally, if the process goes on there is continued wasting, more pronounced constitutional disturbance, hyperpexia, etc., and breaking down of the tissue, involving bronchii and alveoli of the lung and resulting in that peculiar suppurative called caseation, if we examine such a patient at the end, upon the post-mortem table, we find cavities, caseous matter, indurated places and other evidences of inflammation. There is still another form, called *chronic*, in which there is the same result but the march is much slower, the constitutional disturbance also is put off for a long period, but after awhile, if the patient live long enough, the same condition of breaking down—caseation and induration occurs, and we have about the same morbid anatomy for chronic phthisis pulmonalis. Now it occurred to us in common with many that these several conditions could not possibly be identical with either that condition of bone or peritoneal disease where no bacillus is found, or

with general tuberculosis, a general or constitutional disease which exists from the beginning. It occurred to us also that phthisis pulmonalis could not be exactly the same clinically as the disease in the lower animals which is induced by inoculation, and therefore we began to look about for some other cause or causes. In other words, it seemed incomprehensible to me as a clinician, and to Dr. Gibbs as a pathologist, that this *one bacterium* could possibly be alone, the cause of these several complex diseases, because, as you know, reasoning from analogy that each of the specific fevers and like diseases show pretty constant phenomena, and so on, are alike or nearly so, and although there may be a seeming connection between some forms, perhaps, as between the typhoid condition and typhoid fever, yet the causes are not necessarily alike. We therefore, while not contending against the universal existence of the bacillus tuberculosis, think it probable that it is more of a concomitant or resultant in determining certain conditions. This thought, however, is not new; that something else beside the bacillus operates in this disease, for it was suggested by our worthy presiding officer, Dr. N. S. Davis, in 1882, in a paper before the American Medical Association, in which he said that there must be some chemical or biochemical action besides this bacterium to account for such conditions and courses; and many other clinicians have expressed the same doubt. But the thing is to work it out. One more word, concerning the infectious character of the disease: it is argued by clinicians in Europe and a great many in this country, that dry sputum when breathed by an animal or man will produce phthisis pulmonalis! this is true! for we have produced the disease in monkeys by insufflation of sun-dried sputum. In this way we have produced true acute and subacute phthisis pulmonalis, the disease being located in the *lungs*, while by inoculation of monkeys the disease produced has been general, infecting the spleen, liver and other organs, and least or not much at all, the lungs.

It is stated by several bacteriologists and pathologists, even by Koch, I think, that if you dry sputum in the *sun* the virulence of the bacillus is destroyed. We have also found this to be true. Yet we have thus dried the sputum in the sun, and been able to produce the disease in monkeys by insufflation. Does not this seem to indicate that there must be *something* back of the bacterium which is an active agent? Will the absolutely dead and destroyed bacillus produce this effect? We were therefore by this led strongly to think that there is a bio-chemical action in this disease, determining the particular sort of degeneration and suppurative, known as caseation. This then is the main idea in our view and, moreover, we consequently believe that when the d

the lung tissue there the poison is generated, induced by long continued inflammatory changes having taken place. We also believe that ordinary subacute phthisis pulmonalis and some other forms are perhaps similar in their nature to what was called in the old fashioned parlance, scrofulosis. Now with such views we began using different things locally by inhalation to stop if possible the formation of the caseating process and source of chemical action.

It is unnecessary for me to tell you of the large number of experiments, mostly failures, which we have instituted; we used the several gases disseminated in different ways, hydrogen, oxygen, carbonic acid, hydrofluoric acid, etc., with sulphuretted hydrogen; through accident, we discovered that it is a most virulent and subtle poison, one of our assistants in the laboratory was almost killed by it, besides a couple of monkeys killed outright. So we went on trying the gases, and finally settled upon chlorine, first used in 1828. From a study of its chemical nature as far as known, and from the fact that it is more or less combined with so many of the well known chemical reagents that are in use, it seemed to suggest itself to us as being very desirable for our purpose, but by causing so much irritation when inhaled, inducing so much inflammation by contact with animal tissues, it became a question whether we could introduce it or not; we tried a great many methods. First, mixed with air in small proportion and so on, and after killing a few monkeys and guinea pigs, we found after awhile that these animals could inhale the gas in the proportion of 1-40,000 of air; but this dilution we discovered was insufficient to destroy the virility of the sputum, so we increased the quantity of the mixture until obtaining one that would destroy the activity of sputum, so that an animal inoculated with it was not affected. We found that with a mixture of about 1-4000, (by exposure for a few moments) we would destroy the virulence of sputum, so that we could inoculate animals with such sputum without producing any disease. Observing, as we thought, that hydrochloric acid and hypochlorous acid was evolved very soon after the liberation of chlorine gas in the air, probably accounted for its irrespirability and was the cause of the irritation, because the monkeys died from common inflammation of the whole respiratory lining. This afforded very good study, however, because there was general broncho-pneumonia produced, therefore we felt as though we must go on very carefully and not induce such a condition in the human being.

After trying many different things to neutralize the by-products we succeeded in accomplishing the purpose by using a solution of chloride of sodium. We began with chlorine water spray, but found by experiments with guinea pigs in a gas cage that sprays did not penetrate into the

lungs readily, that is without very long exposure although gas was evolved, all of which seemed to be unsatisfactory. It is possible, however, that the local effect of anything may be continued for a long time on the respiratory tract, beyond the place of contact, but we could get no chemical reactions in animals' lungs by using sprays, unless we used some substance subsequently giving off the gas. We obtained some effect from the spray of peroxide of hydrogen, which, after being diffused in the air of the gas cage, seemed to split up; also with chlorine water, which after awhile left the chlorine gas in the air, but we could not thus destroy the sputum. We therefore continued with our experiments in the use of chlorine gas, and found that with chloride of sodium spray well diffused, animals could inhale chlorine for a considerable length of time; and after trying it thoroughly on animals we began experiments on human beings with satisfactory results. Our idea was to stop the formation of the virus, whatever it might be, whether a ptomaine, a leucomaine or a toxalbumin, etc., and thus to stop the progress of the disease at these points, believing that phthisis pulmonalis is essentially a local disease. But we found after awhile that this plan would not stop the process altogether although it would check it! In the monkey, it would only feebly act in checking the course of the inoculated disease. But if we could manage to set up phthisis pulmonalis in monkeys by exposure, or from the insufflation of the dried sputum, or in menageries, we could prolong the course of the disease very much indeed by the gas. Constitutional disturbances would come on after awhile, however.

Turning attention toward meeting constitutional effects, the iodides of a great many chemicals were used, also chlorides and sulphides. We at first used them by the mouth, which brought serious events. On account of the changes which chemicals undergo in the stomach and intestinal canal we thought it better to use them by hypodermic injection if possible. There are reports in the literature of medicine from the last century, that iodine was valuable, but an irritant, and would produce abscesses, which it did in our experience. We thoroughly tried it, but had abscesses, which caused the death of the animals, but we found by accident that the abscesses were due to chemical impurities. After having the iodine resublimated by Dr. Clark we had no difficulty from abscesses, unless we used enormously large doses on animals. The same thing we found to be true of the chloride of gold and sodium and permanganate of potassium. The idea of using iodine came to us first from the fact of its solvent action upon the lymphatic glands and tissues generally in all of those diseases which so closely resemble phthisis pulmonalis clinically. We have used also the arsenite of potassium, but found that the poisonous effect was so great that it could not be

continued for any considerable length of time. We observed that after using iodine a certain length of time, a certain condition, iodism, took place which prohibited its further use; animals and man would have diarrhoea, vomiting, and would refuse food, etc. It is astonishing how much a little animal like a guinea pig can stand of these chemicals. These symptoms coming on soon made it necessary to have something else to hold the effect as it were. Taking our experience in the action of chloride of gold and sodium on dead tissues in general, we hit upon that, after failure with bichloride of mercury and other salts, and used it locally and by injection. Although it is said by surgeons that if you use hypodermic injections aseptically no abscess will follow, yet you will find that bichloride of mercury used hypodermically may produce abscess. This is not the case with chloride of gold and sodium if chemically pure, which, as you know, has been used for years as an alternative. We began by small doses and gradually increased them. We inoculated a number of guinea pigs, first with these chemicals, one series with iodine and one series with gold, and after doing that for a week or so until we noted physiological effects, we then inoculated them with well known virulent sputum and found to our astonishment that the pigs did not take the disease. We repeated this with another series, with the same effect, until we have now a number of very healthy pigs that have been inoculated with iodine and gold and with undoubted virulent sputum as proven by control animals. Just which is the better, of course has not been determined yet, for there are a great many things to learn. Unfortunately, the further we go into such a subject the more we appreciate that we know but little. We have been trying since, in continuance of our work, to trace out the poison, whatever it is. If we are right in this idea that it is a toxalbumin, a ptomaine, or a lencomaine, we want to isolate it. We want to get it out so that we can show it and test it and have it exposed in its true form, just as we can get crystals of strychnine, and we do not feel that the work is done unless the poison can be thus shown. We therefore feel that we are in the first part of the work only until we can show what part of these extracts lie at the bottom of the causation.

We are now engaged in making extracts—I can only hint at it, can only say that some of the results we have had from these extracts have been astonishing to ourselves, and if we can continue and perfect these investigations the probability is that in a year, or perhaps less, we may be able to isolate the particular poison or poisons which produce this disease, or which are generated in the body and keep up the disease. These extracts will produce it in the guinea pig; but whether they will do it *every time* we do not

know; we have not had time to test it thoroughly.

I suppose some of you may want to know what success we have had with human beings. We have tried to be very careful about making promises, although we have been published in the papers very much more than we anticipated or desired and there have been a great many exaggerated statements made. But of course you would like to know what success we have had thus far. I cannot give you the details of the cases to-night, we expect to publish some case histories in a short time. Of the cases of so-called general tuberculosis we have treated altogether about four well-marked cases; two of which died without showing any effect of treatment, one of them is certainly very much better, and the other case is simply held in abeyance, so far as we can observe. We have treated a number of cases of phthisis pulmonalis, including what Dr. Gibbs spoke of as the tuberculous form and the pneumonic form. We have had in all about twenty-two cases under observation for about two to three months with about six so called cures, taking all the several cases together, but there has not been time enough to tell whether these people have been thoroughly cured or not. In one case there was very decided laryngeal ulceration, which was seen by several medical gentlemen, in that case the cicatrix was so complete that it could be seen with the laryngoscope, just before she went home about Christmas practically well; her physician continues the hypodermic injection about once a week. One case I have in mind was a man in whom the upper left lung was breaking down, as was evidenced by moist and gurgling râles, so that there could be no mistake about it. He was examined by two or three others besides myself. This man has been under treatment since September and he has now an injection about once a week or ten days, but has practically gone from under the treatment. Another case, that of a young girl, who has gone home, seems to be lasting, the last advice is that she has remained well with scarcely any cough, merely a little hacking in the morning. In her case the diagnosis had also been made out by physicians before she came to us. Another case is that of a teacher who has resumed her school duties since January, she still coughs a little in the morning but has no elevation of temperature now and is gaining flesh and strength. Another case was that of a man whose disease was of a more chronic form; he left the hospital in a very much better state; he eats well and has no elevation of temperature whatever, no nocturnal diaphoresis, or anything of that kind. Of course this does not prove anything until more time elapses.

We have now about thirty-five cases under treatment, some of which are doing very well! There are two or three of them termed "caseous

pneumonia," that are not doing very well. The one case of tuberculosis which I mentioned is a case which several gentlemen outside the staff saw in the hospital; we thought of giving up the treatment, because there was no chance, for it is undoubtedly a case of general tuberculosis. But after one or two relapses she has been getting better, and when I left home she had been sitting up considerably for a number of days past; although she has elevation of temperature she has no nocturnal diaphoresis, her appetite has returned and she expectorates only about two drams of mucous in twenty-four hours, with no pus. We have one case of a young boy in the hospital, which is very promising and very interesting inasmuch as the probability is that he had pneumonia followed by abscesses of the lungs first, and then caseation of the lung. Another case was of pneumonic abscess followed after a time by the presence of tubercle bacilli in the sputum; on account of the deep location of the abscess, I did not open into the lung. I was afraid to cut through such a large amount of lung tissue to reach it. I therefore put him under this treatment, and he is slowly recovering from the abscess of the lung.

There are some other chemicals we have been using lately that may prove more valuable than iodine and chloride of gold. Of course the experimentation is far from complete, but one of them especially bids fair to be more promising than gold. The general plan of treatment seems to us to hinge on the use of chlorine gas to stop the caseation as far as possible, and cut off the origin of the poison, which thence is circulating through the system. In the early stage of disease, before much caseation, we do not think it is necessary to use the chlorine gas too freely, but instead the iodine, for its well known effect upon chronic inflammation.

I would say in regard to the manipulation of chlorine gas that it is a very simple thing but it needs some care. The chloride of sodium spray should be put into the room first, and the air thoroughly laden with it before the chlorine gas is evolved. At the hospital we use about 1-20,000 up to 1-1000. The first dose should be quite small for cases of laryngeal phthisis. In cases where there is ulceration chlorine gas in a room seems much the better way. If, however, there is only tumefaction the mixture of sol. of chloride of sodium and chlorine water chemically pure, is quite sufficient from an inhaler. The mixture of the two was suggested to us by Dr. Ingals, of your city. Before that, we used two tubes one containing chlorine water and the other the chloride of sodium solution. We had tried mixing them before but had always obtained a precipitate, and we therefore thought the two were incompatible, but we found out afterwards that it was because of exposure to light and long standing,

and if the mixture be used immediately we could get good results. So in cases of laryngeal phthisis of all forms, we should recommend that an inhaler be used.

We are certainly very much obliged to the profession of Chicago for the attention that has been shown us. When we started out, we had no idea that we were going to interest the profession of Chicago to such an extent, and as I said, we are very grateful for the attention we have received, and feel that we do not deserve it. We have not accomplished anything as yet, we have only started! We have nothing definite to promise and we only hope that all of you may aid us in every way possible by your criticisms and by your crucial tests, for that is the only way in which this problem can be solved.

ORIGINAL ARTICLES.

ADDITIONAL COMMUNICATIONS CONCERNING A REMEDY FOR TUBERCULOSIS.¹

BY PROFESSOR R. KOCH,
OF BERLIN.

The following translation of Mr. Doctor McDill represents perfectly the original treatise.

PROF. EHRLICH for PROF. KOCH.

Berlin, Jan. 17, 1891.

Since the publication, two months ago, (see *Deutsche Med. Wochenschr.*, No. 46 a) of my experiments with a new method of cure for tuberculosis, many physicians have obtained the remedy and have thereby been enabled to become acquainted with its properties by personal experiences. As far as I review the publications which have appeared, together with the communications to me by letter on this subject, my statements have, upon the whole, found full corroboration.

It may be considered as generally accepted that the remedy has a specific action upon tuberculous tissue and that it consequently can be utilized as a very subtle and reliable reagent for the bringing to light of the hidden, and the diagnosing of the doubtful tuberculosis processes. Also regarding the curative effect of the remedy, it is reported by the majority of observers that, despite the comparatively short duration of the treatment, a more or less extensive improvement has occurred in many cases. In not a few cases that have been reported to me a positive cure is claimed. Only here and there has been made the statement that the remedy might not only prove dangerous in cases too far advanced, as will be readily ad-

¹ Translated from the *Deutsche Medicinische Wochenschrift* of January 15, 1891, by John R. McDill, M.D., of Milwaukee, Wis., now in Berlin.

mitted, but that it directly favors the tuberculous process and is therefore *per se* harmful. I myself have for the past month and a half had an opportunity of gaining further experience concerning the curative effect and diagnostic uses of the remedy, by the observation, in the City Hospital in Moabit, of about 150 cases of the most varied forms of tuberculosis, and can only state that all that I have seen of late agrees with my former observation, and that I have no alteration to make in my previous report.²

As long as it was a question of testing the correctness of my statements, it was not necessary to know what the remedy contained or whence it originated. On the contrary, the trial was likely to prove the more unbiased the less was known of the remedy itself. But now that the proof has, as seems to me, been offered in sufficient quantity and has resulted in establishing the value of the remedy, the next problem to be worked out will be, to study the remedy beyond the extent to which it has hitherto been applied, and if possible, to employ the principles which have led to its discovery, in other diseases. This problem requires, self-evidently, a full knowledge of the remedy, and I, therefore, consider that the time has arrived to make the necessary statements in this direction and which will appear in the following. Before I touch upon the remedy itself, I think it advisable to the better understanding of its mode of action, to shortly indicate the road by which I arrived at its discovery.

When a healthy guinea pig is inoculated with a pure culture of tubercle bacilli the inoculation wound, as a rule, closes and appears to heal during the first few days, but in the course of ten or fourteen days there forms a hard nodule which soon breaks open and becomes an ulcerating surface which persists until the death of the animal. But the case is very different when a guinea pig is inoculated which already has tuberculous disease. For this purpose are best suited animals which four to six weeks beforehand were successfully inoculated. In such an animal the small wound of inoculation closes at the beginning, no nodule forms there, however, but on the next or second day a peculiar change takes place at the injection spot. This place grows hard and becomes of a darker color, and then this change is confined not merely to the vaccination site, but spreads about its neighborhood to a diameter of 0.5 to 1 cm. During the following days it appears more and more evident that the skin thus changed is necrotic; it is finally thrown off and there remains a superficial ulceration which usually heals rapidly and permanently

without the neighboring lymph glands becoming infected.

The inoculated tubercle bacilli thus act quite differently upon the skin of a healthy than upon that of a tuberculous guinea pig. Now this striking effect does not by any means belong exclusively to the living tubercle bacilli, for it is brought about in much the same manner by the dead ones, and it is unessential whether they are destroyed, as in my first attempts, by low temperature of long duration, by boiling heat or by certain chemicals.

After this peculiar fact was found, I have followed it out in all directions, and there then further resulted that (abgetödet) pure cultures in which the tubercle bacilli have been killed, after having been triturated and suspended in water, could be injected in large quantities under the skin of healthy guinea pigs without anything ensuing beyond a local suppuration. Tuberculous guinea pigs on the other hand are killed by the injection of even very small quantities of such suspended cultures, and this occurs, according to the dose applied, in from six to forty-eight hours. A dose which is just insufficient to kill the animal can cause an extensive necrosis of the skin, about the place of injection. Now, if the suspension (Aufschuemmung) be still further diluted until it is barely visibly turbid, then the animals remain alive, and if the injections are continued at intervals of one or two days there soon occurs a marked improvement in their condition; the ulcerating inoculation wound grows smaller and finally cicatrizes, this, without such treatment, never is the case; the swollen lymph glands diminish in size; the general nutrition improves and if the disease process is not too far advanced and the animal does not die of adynamia, it comes to a stop.

Hereby was given the foundation for a curative treatment of tuberculosis. To the practical application, however, of such suspensions (Aufschuemmungen) of "killed off" (abgetödet) pure cultures of tubercle bacilli, the objection offered itself that at the sites of injections the tubercle bacilli are not absorbed, nor do they in any other way disappear, but that they remain lying unchanged for a long time and form greater or smaller suppurative foci.

That which, in this proceeding, has the healing influence on the tuberculous process had consequently to be a soluble substance, which, by the fluids of the body surrounding the tubercle bacilli, is in some manner extracted and then quite rapidly brought into the circulation, while that which has the suppurative effect apparently remains behind in the bacilli, or goes into solution, but very slowly.

The main point, therefore, was to institute out-

² Regarding the permanency of the cure, I should like to mention here that of the patients which I had for the time being pronounced cured, two have returned to the Moabit Hospital for further observation, and that for the last three months no bacilli have been found in their sputa; the physical signs also have gradually disappeared in these cases.

³ Injections of this nature are among the simplest and surest means of producing suppurations which are free from living bacteria.

side of the body the process which took place within, and if possible to extract and isolate from the tubercle bacilli the healing substance. This problem has required much trouble and time, but I finally succeeded in separating the efficacious material from the bacilli, with the help of a 40 per cent. to 50 per cent. of glycerine solution. It is with fluids thus procured that I have made the further experiments on animals and finally on human beings; these fluids have been given to other physicians for the repetition of the experiments.

The remedy with which the new treatment for tuberculosis is carried on is therefore a glycerine extract of the pure cultures of the tubercle bacilli.

Out of the tubercle bacilli there, of course, passes into this simple extract not the efficacious substance alone, but also all the other substances which are soluble in a 50 per cent. glycerine solution, and, therefore, there are found in it a certain quantity of mineral salts, coloring matters and other unknown extractive matters. Some of these ingredients can be rather easily separated. The efficacious substance is insoluble in and can be precipitated by absolute alcohol, to be sure not pure, because together with it are precipitated other extractive materials which are also insoluble in the alcohol. The coloring substance it is true can be removed, so that it is possible to procure from the extract a colorless dry substance containing the active principle in a more concentrated form than the original glycerine solution. For practical application, this purification of the glycerine extract offers, however, no advantage, because the substances thus removed are indifferent to the human organism and therefore the purifying process would only render the remedy unnecessarily more expensive.

The constitution of the efficacious material is so far a mere matter of conjecture. It appears to me to be a derivative of albuminous bodies and clearly related to them, and does not belong to the group of so-called tox-albumins, because it bears high temperatures and passes easily and rapidly through the membrane of the dialyzer. The quantity of the substance contained in the extract is apparently very small; I estimate it at fractions of 1 per cent. We have then, if my supposition is correct, a substance the effect of which on tuberculously diseased organisms far surpasses what is known to us of the most powerful drugs.

As to the manner in which we have to imagine the specific action of the remedy on tuberculous tissue, different hypotheses can, of course, be entertained. Without wishing to assert that my opinion affords the best explanation, I believe the process to be the following: The tubercle bacilli produce by their growth in living tissues, the same as in artificial cultures, certain substances which influence the living elements, the

cells, in their neighborhood in varied but always harmful manner. Among them there is one substance, which in certain concentration, kills living protoplasm and so changes it that it passes into the state termed by Weigert coagulation necrosis. In the tissue grown necrotic the bacillus then finds such unfavorable conditions of nutrition that it is unable to keep on growing and under certain circumstances even dies off. In this manner I explain to myself the striking coincidence that in organs recently affected with tuberculous disease,—for instance, in a guinea pig's spleen or liver, which is full of disseminated gray nodules—we find numerous bacilli, while they are scarce or altogether absent when the enormously enlarged spleen consists almost entirely of white substance in a state of coagulation necrosis, as is often found after the death of guinea pigs from tuberculosis. Therefore the individual bacillus is unable to cause necrosis to any great distance, for as soon as the necrosis has reached a certain extent, the growth of the bacillus decreases and thereby also the production of the necrotizing substance; hence there results a kind of mutual compensation which causes the vegetation of individual bacilli to remain so remarkably limited, *e. g.*, in lupus and scrofulous glands, etc. In such cases the necrosis ordinarily concerns only a part of the cell, which then in its further growth takes the peculiar form of the giant cell; I thus, from this point of view, accept the explanation first given by Weigert of the formation of giant cells.

If the quantity of necrotizing substance was now artificially increased around the bacillus, the necrosis would extend to a greater distance and thereby the conditions of nutrition for the bacillus would become much less favorable than usually is the case. On the one hand, then, the tissue grown necrotic to a greater or less extent would perish, become detached and wherever possible carry away with it and extrude the enclosed bacilli; on the other hand the bacilli would be so greatly disturbed in their vegetation that they would be much more liable to die off than under ordinary circumstances.

The working of the remedy to me seems to consist in the production of just such changes. It contains a certain quantity of the necrotizing substance, a sufficiently large dose of which damages certain tissue elements also in the healthy subject—possibly the white blood corpuscles or cells closely related to them, and thereby produces fever and the entire complex symptoms. In the tuberculous subject, however, a very much smaller quantity suffices to cause in certain places, namely, where tubercle bacilli vegetate and have already impregnated their surroundings with the same necrotizing substance, necrosis of cells, more or less extensive, and in connection therewith consecutive symptoms in the whole organism.

In this way we can, at least for the present, explain the specific influence which the remedy, in quite definite doses, exercises on tuberculous tissue; next the possibility of raising these doses so remarkably fast; and finally the curative effect which undeniably exists in those cases which are but moderately favorable.

A STUDY OF STERILITY, ITS CAUSES AND TREATMENT.

Being an Essay which received the First Prize of the Alumni Association of the College of Physicians and Surgeons, Baltimore.

BY THOS. W. KAY, M.D.,
OF SCRANTON, PA.

(Concluded from page 229.)
TREATMENT.

1. *Nonproduction.*—*Male.*—(a.) Should the testes of the male be congenitally absent from the scrotum there is a possibility of their being present in the abdominal cavity, but in either case if aspermia or azoospermia exists, treatment is useless. Should spermatozoa exist in small quantities the same remedies can be used that are employed in early decay. These can also be used in cases of retarded development.

(b.) Where inflammatory or other troubles have produced destruction of the glandular structure, restoration of the destroyed tissue is impossible; but under iodides and mercurials with counter-irritants and electricity, the inflammatory deposits may be absorbed and the arrested secretion from the remaining healthy portions reestablished.

(c.) When sterility in the male is accompanied by atrophy or softening coincident with varicocele, hernia, or other benign tumors, the prognosis is good, if the individual will submit to surgical treatment in time. The tumors should be extirpated and the testes injured as little as possible. In all cases of hernia where a truss is not suitable the radical cure should be undertaken. Of all the methods used for varicocele the best is ligating the veins above and below, by the open method, and dividing them between. Hydrocele should be first treated by withdrawing the fluid and injecting irritating substances, after which, if a cure is not effected, more radical measures can be adopted. For malignant tumors, thorough extirpation has to be resorted to and the prognosis is very unfavorable for future posterity.

(d.) If sterility is subsequent to some constitutional disease, attention must be directed to building up the general health. A sea voyage, a trip to the mountains, sea bathing, or a stay at some chalybeate springs will be found beneficial in anæmic or debilitated persons.

In obese and plethoric subjects the saline springs will be preferable, while a course of laxatives, careful dieting and regular exercise will exert a beneficial influence. Should the cause

be traced to masturbation or excessive venery, bromides must be used, while the will power is appealed to and the patient removed as far as possible from all exciting causes.

Debility of the sexual organs can be best overcome by cold douches and electricity, while the phosphides, nuxvomica, and cantharides are employed internally.

Female.—(a.) Congenital absence of the ovaries can not, of course, be remedied, and non-development is almost as hopeless, though there is reason to believe that the use of electricity and massage, long continued, may stimulate the development of the glands. Where dislocation of the ovaries depends on uterine displacements it should be treated by attending to the false uterine position. If the ovary alone is dislocated it can frequently be treated by a pessary, unless in the inguinal canal, when it should be replaced and supported by a proper fitting truss.

(b.) Little can be done when atrophy of the ovaries follows wasting diseases, except to use tonics and such remedies as are used in atrophied testes, hoping thereby to cause development of such follicles as have escaped the inflammatory process. Much, however, can be done to prevent inflammatory troubles by preventing early marriages. Women, as a rule, unless well developed, should not marry under twenty years of age, and in many cases it is best to wait until the twenty-second year. In pelvic inflammations, where exudation has taken place, it is well to withdraw, by aspiration, what fluid can be obtained and thus abort the trouble. Dr. Hardon, of Atlanta, Ga., speaks highly of this treatment, and I have seen the happiest results follow its use. Where due to syphilitic infection the inflammatory deposits must be treated by iodides and mercurials while tonics are given to build up the general health. Where atrophy of the ovaries is due to contraction of inflammatory deposits, which dislocate or compress the ovaries, much benefit can be obtained from the long-continued use of hot water vaginal injections, massage and galvanism. Vaginal and rectal suppositories, containing iodine, iodoform, or one of the iodides, can also be used with advantage. With the local treatment we should also use tonics and such remedies as are best calculated to build up the constitution.

(c.) Where malignant growths affect the ovaries, early and complete removal must be resorted to, but if the growth is benign, the operator should, if possible, leave as much of the ovary as appears to be healthy, in the interest of future generations.

(d.) The sterility attending anæmia, chlorosis and other constitutional affections must be treated on general principles. Tonics, baths, chalybeate waters, voyages, change of scenery and surroundings, can all be used, while good and nutritious

food must be furnished and regular out-door exercise enjoined. Where the persons are addicted to the use of drugs they will have to be gradually weaned off and some substitute used till the physical and moral nature is sufficiently strong to enable them to abstain.

In cases of obesity, rich, saccharine, fatty and starchy foods must be forbidden, regular and daily out-door exercise required, and sea bathing and saline waters advised. In the way of medication aloes, iron, nux vomica, and phosphorus can be employed advantageously. Desprès relates cases where the application of electricity produced sexual excitement with a discharge of vaginal and uterine secretions, and it is more than likely that the same agent will be found of use where non production of ova is due to a sluggish condition of the female genitalia. Little can be done by the physician in inherited sterility except to pay attention to the general functions of the body, but he should, wherever he can act as the family adviser, impress on his patients the evils of inter-marriage, and do all that he can to prevent such unions.

2. *Nonunion. Male.*—(a.) Any absence or occlusion of the ducts situated between the testes and the urethra is naturally out of reach of the surgeon, unless the occlusion is due to pressure from a tumor of the cord or elsewhere, in which case it can be readily removed. The causes of non-union in the male are fortunately situated, as a rule, in the urethra, and these can generally be remedied. In urethral fistula, epispadias, and hypospadias, the defect can be remedied by a plastic operation. Phymosis, stenosed meatus and dilated meatus can also be easily remedied by simple operations. It is in strictures of the urethra, however, that the surgeon has to employ his ingenuity, and wide differences of opinion exist as to the best methods to employ. Soft stricture usually yields readily to dilatation, but the fibrous stricture should be treated by urethrotomy and electrolysis. Otis, of New York, prefers internal urethrotomy; Stein, of New York, thinks gradual dilatation best; Keyes, of New York, practices external urethrotomy for strictures from injuries; Lavaux, of Paris, claims a new method which he calls "divulsion progressive," where a cure can be effected in eight days; and every town of any size now has its ardent advocate of electrolysis. Should the breadth of a fibrous stricture be narrow it may be advantageously excised by external urethrotomy and the two portions of the urethra carefully drawn together and united by sutures.

(b.) Though the gonorrhoeal poison is one of the most potent factors in producing sterility, yet it probably affects the vitality of the spermatozoa very little as they pass through the urethra. It is well, though, in every case to check the discharge as soon as possible, and for this I have

found injections of creolin or of sublimate solutions among the best remedies.

(c.) The use of artificial means by the male to prevent conception can not be too severely condemned, for they are injurious both morally and physically. Abstinence from coitus, and coitus only about midway between the two monthly periods are the only legitimate means to be employed, where there is a desire to avoid conception.

(d.) In individuals of excitable dispositions, where orgasm comes on before that of the female, bromides can be given, but in time each individual will learn the other's disposition and be able to hasten or delay orgasm till the proper moment. If this is not accomplished in a reasonable length of time, it may be well to separate the parties for a longer or shorter period, at the end of which time the difference in disposition will probably not be as great. Where neuroses of the genital tract exist there will generally be found some tenderness, or it may be a stricture of the urethra. In either case attention must be directed to the seat of the trouble. If orgasm seems to be retarded by exhaustion of the nerve centres nothing will be found better than phosphide of zinc and nux vomica. Where the trouble seems to be due to a dilatation of the dorsal vein of the penis, simultaneous injections of ergotin by the side of the vein will be found useful. Jamin, of Paris, reported a case where imperfect erection was cured by the surgical treatment of an accompanying varicocele. Vidal de Cassis reported a similar case and I have succeeded in curing another case by the same treatment.

Female.—(a.) All abnormal conditions of the ovaries and of the ova which prevent the escape of the ova or the subsequent entrance of the spermatozoa are irremediable. So also is absence or imperfect development of the tubes and absence of the uterus. In cases of double uterus operative interference is not called for, nor is it in double vagina unless the septum prevents coitus. Where there is partial or complete absence of the vagina, with a normal uterus present, an artificial vagina can be made by carefully dissecting between the bladder and rectum so as to avoid injury to these organs. In unmarried females tents will have to be used occasionally to keep it from contracting, but after marriage the male organ will usually render the use of the tent unnecessary.

The discovery of an imperforate hymen is usually made at puberty, and is easily remedied by incising, but all antiseptic precautions must be used to prevent septic absorption. Should coitus be prevented by a rigid hymen or an abnormal condition of the vulva, a slight and harmless surgical operation will set all to rights.

Atresia of the cervical canal is best operated on by a trocar, and dilators used afterwards. If

hæmatometra is present the same care must be used as recommended in operating on hæmatocolpas, for septic poisoning is exceedingly easy after the operation. Stenosis of the cervical canal can be treated by incision, or by dilating with instruments for that purpose, but the best and most permanent results are obtained from the occasional use of tents.

For absence or abnormal shortness of the intra-vaginal portion of the cervix there is no remedy. Where uniform elongation or hypertrophy of the cervix exists amputation must be resorted to, but in the operation care should be used to unite the mucous membrane of the cervical canal to that surrounding the cervix so as to prevent subsequent stenosis. In sterility due to stenosis or flexions the "Outerbridge dilator" will be found of service, if introduced several days before the menses make their appearance. Where hypertrophy of the cervix is confined to only one side, amputation can be practiced or the convex portion of the cervix can be incised so as to remove the obstruction. Conical and nozzle-shaped cervixes must also be amputated. In cases of lacerated cervix or lacerated perineum the duty of the surgeon is to repair the injured part as soon as possible.

In all displacements of the uterus an effort should be made to restore the normal position.

Prolapse can be treated by massage, hot douches, astringent tampons, pessaries, supporters, or some of the surgical procedures to be mentioned hereafter. Where flexions exist tents should be used to soften the uterine tissue and straighten out its axis, after which intra-uterine stems, tampons or pessaries should be used to keep it in its normal position. Versions can often be treated by tampons and pessaries, and Bouilly, of Paris, recently reported eighty cases of retro-deviations treated successfully by pessaries; of this number three had subsequently become pregnant. Should, however, the displacements be of long standing it will be well to resort to surgical interference. Alexander has devised a means of shortening the round ligaments of the uterus, which has been modified somewhat by Polk and Wylie. This operation gives the best results for simple retro-deviations, but it has also been used in prolapse. In the latter case it is best to accompany it by some operation for narrowing the vagina or increasing the perineal support. In a case of prolapse Freund, of Strassbourg, opened Douglas' cul-de-sac and attached the fundus uteri to the peritoneum of the sacrum. This he calls retro-fixation. Vento-fixation consists in opening the abdominal cavity and attaching the uterus to the abdominal parietes. It is steadily growing in favor and has the hearty support of such men as Lucas-Championnière, Polaillon, and Terrier, of Paris; Säger, of Germany; Kelly, of America, and many others. It

gives the best results in cases of simple retroversion, but has been used in nearly all displacements. Piqué, following the operation Olshausen, has, where the uterus was bound down, opened the abdomen, divided the bands and attached the uterine ligaments to the abdominal parietes. The result was good, but it might be well to adopt the method of Erich and forcibly separate the adhesions by a large steel sound introduced into the uterine cavity. It seems also that the safety of these operations might be increased by incising only as far as the peritoneum and suturing without opening the abdominal cavity. Contracted pelvis is a rare cause of impediment to the entrance of the semen, and when it is can not be remedied.

Acquired stenosis or atresia of the genital tract must be treated in the same way as the congenital form, and usually gives better results.

The evil results of inflammatory deposits about the uterus and its appendages have been dwelt on in speaking of the causes of sterility. When the acute stage has passed such remedies should be used as will favor the absorption of the deposits. Copious injections of hot water, in both vagina and rectum, are found very serviceable in producing these results, but they must be long continued to produce the best results. Tampons of glycerine with or without iodine, or iodide of potash also exert a favorable influence. Rectal and vaginal suppositories of iodine, iodide of potash, or iodoform have yielded excellent results in my hands, when combined with tonics and hot-water injections.

In some cases local blood-letting will be found serviceable. With all these remedies absolute abstinence from sexual excitement must be enjoined.

Electricity has been introduced by Dr. Georges Apostoli in the treatment of these affections, and its long continued use in chronic and subacute cases has been followed by the most excellent results.

Engelmann and many others, both here and abroad, testify to its efficacy.

Major Thure Brandt, of Stockholm, was the first to use massage in uterine affections, after which it was practiced by Dr. Sahlin of the Stockholm medical school. In 1870 Dr. Nostroöm, of Paris, became interested in the subject, and after carefully studying it introduced it into Paris in 1872, since which time it has been diffused over the whole civilized world.

It has been used for uterine displacements, metritis and ovaritis, but its most satisfactory results have been made in peri-uterine exudates of long standing. Semanikoff, of St. Petersburg, reports favorably of it, as do also Profs. Jackson and Martin, of Chicago, Drs. Smith and Athill, of England, and many others. Boldt, of New York, calls attention to the fact that great care must be

used where accumulations of fluid exist in the tubes. To get satisfactory results massage must be carried out by the gynecologist himself, and persevered in for a long time. Only chronic and subacute cases should be subjected to treatment, and where the finger of the operator is not long enough to reach the deposits he may resort to the obturator of Wissenberg, the end of which may be covered with rubber if much tenderness is experienced.

When hydro-, hæmato-, or pyo-salpinx exist, they may be overcome by putting the patient under an anæsthetic, dilating the uterus, breaking up what adhesions exist, and thoroughly curetting the endometrium, especially around the openings of the tubes. Intra-uterine galvanism is also useful, and cases have been reported where the obstruction in the tube has been overcome in this way. In the early stages of salpingitis it is well to follow the treatment of Dr. Mangan, of Marseilles—use rest, sedatives, and cold to the abdomen, while hot vaginal injections are employed, and when the case becomes more chronic apply medicated glycerine tampons to the cervix and iodoform pencils to the interior of the uterus. With these remedies it is well to combine tonics and baths.

Should vaginismus be the cause of sterility the remedies employed must be adapted to the cause of the vaginismus. Solutions of lead, silver and zinc may be employed for the inflammatory process, while cocaine, belladonna and morphia will relieve the irritation and pain. Coitus under chloroform has been advised but does not relieve the trouble. Gradual dilatation with specula has been used, but probably the best remedy is to excise the hymen close to its insertion. When vaginismus is due to uterine fibroids galvanism will usually effect a cure if sufficiently long continued.

In all cases where non-union of the ova and spermatozoa is due to hypertrophy or tumors of either the external or internal organs of generation, the surgeon should remove the cause if possible. The fact of sterile women becoming pregnant after the removal of uterine or ovarian tumors is well known to all.

Should the acid secretions of the vagina be injurious to the spermatozoa, boracic acid will be found to be an excellent remedy. Potter, of Buffalo, employs vaginal tamponnement with this remedy in cases of sterility, and claims good results from its use. Kisch recommends a warm aqueous saccharine solution rendered alkaline by caustic potash, and Chassier uses a solution of white of egg and phosphate of soda, in which the spermatozoa are said to live for a long time.

Where the impediment seems to be due to a thickened cervical secretion, it will be well to introduce a tampon, saturated with glycerine, several hours before coitus, and remove it before the act is accomplished.

Vaginal catarrh can be best remedied by injections of solutions of corrosive sublimate, creolin and boracic acid, though the astringent metallic salts can be used with advantage, and where much pain exists sedatives and demulcents should be employed. Parvin, of Philadelphia, and Jules Chéron, of Paris, speak in the highest terms of the use of creolin, employed either in solution or as an ointment.

The diagnosis of acute endometritis is usually easy, but where chronic endometritis is suspected it is best to follow the advice of Schultze, of Jena.

This consists in inserting a glycerine tampon against the external os at night, which, on removal in the morning, will have a small quantity of pus on it, if endometritis is present. The cure of simple catarrhal endometritis may be effected by glycerine tampons, and hot douches as recommended by Hermann, of London; or a solution of morphia may be employed with success, according to Sivieček. Where the cases are more obstinate solutions of nitrate of silver, sulphate of copper, tr. of iodine, carbolic acid or creasote can be used with advantage, but better results are obtained from introducing crayons made from tragacanth dissolved in glycerine and water, which contain iodoform, corrosive sublimate, creolin, resorcin or salol. Where the endometritis has become chronic, Dumontpallier uses Canquoin's paste, and Rheinstædter, of Cologne, Dorff, of Belgium, and Bröse, of Berlin, speak in the highest terms of a 50 per cent. solution of chloride of zinc applied to the endometrium, which can be followed in a few weeks by a 20 per cent. solution. With the above remedies tonics must be used, and all agents that are calculated to build up the general system. The treatment of salpingitis has been spoken of before, and the line of treatment mapped out.

Where fistulæ exist, surgical procedures must be resorted to, and it is well, where it is possible, to follow Tait's operation, as it probably gives better results than any other.

(c.) Nothing need be said about the artificial means used by women to prevent conception, except to condemn them as injurious and unnatural.

(d.) It is rare that the physician is called in to treat cases of retarded orgasm or the contrary condition, and when he is, little can be done except to appeal to the moral power while the functions of the body are put in order. In some cases a separation of the man and wife for a lengthy period of time will be found to be very beneficial to both parties, and will overcome the trouble.

3. *Non-implantation*.—Non-implantation after impregnation is due to some trouble in the tubes or the uterus. The treatment of diseased tubes has been spoken of while discussing the union of the ova and the spermatozoa, and it now remains to consider briefly the affections of the uterus.

The prognosis in the undeveloped or atrophied

uterus is poor, and yet, with the long continued use of tents, stimulating crayons, hot douches, electricity, massage, emmenagogues, and strict attention to the general health, much good can be obtained. The treatment of peri- and parauterine deposits has been spoken of in connection with uterine displacements, and endometritis was treated of when considering agencies injurious to the life of the spermatozoa. It remains to say, however, that in exceedingly obstinate cases of chronic endometritis, with or without fungous or other growths of the endometrium, the application of the blunt curette will be found most useful. After its application a solution of the subsulphate or the perchloride of iron should be applied to the endometrium, as recommended by Kay, of Scranton, or the iodized phenol can be substituted with advantage, according to Roony, of Quincy.

In curetting the uterus it is well to remember that paralysis of the muscular walls sometimes takes place, and the instrument seems to pass into blank space. Cases of this kind have been reported by Doléris and Geijl. For implantation of the ovum it is necessary to remove all intra-uterine growths, but where they are subserous or situated in the muscular tissue, the application of electricity should be persevered in, as its results are excellent and little danger attends its application. Ergot has been used subcutaneously, but little good has been obtained from its use. If sterility is due to compression of the uterus from intra-abdominal growths, laparotomy must be resorted to to remove the trouble. If cancer of the cervix is taken in time, its removal will justify a favorable prognosis, but where the disease has attacked the body of the organ nothing can be done in the interest of child-bearing.

In cases of membranous dysmenorrhœa the cavity of the uterus can be dilated and various medicinal substances applied to its interior. The curette has also been used with success, and Winckel has had good results from the application of leeches to the cervix uteri. But in many cases all treatment fails to relieve the trouble, and all that can be done is to see to the general health while sedatives and opiates are employed as required. In menorrhagia and metrorrhagia the cause must be looked for and the case treated accordingly.

MEDICAL PROGRESS.

Therapeutics and Pharmacology.

A NEW MODE OF EXHIBITING SULPHONAL.—DR. DAVID D. STEWART, of Philadelphia (*Medical News*), says that unquestionably the great disadvantage of sulphonal over other recently-introduced hypnotics is its insolubility and consequent slowness of action. As ordinarily administered, dry upon the tongue, or suspended in mucilage, etc., the result, in most cases, is unsatisfactory. Even after a decided dose hours often elapse before sleep is obtained, and, usually, a condition of very annoying semi-somnolence is maintained throughout the greater part of the subsequent day. Unpleasant effects of this sort are so frequent that many physicians are deterred from prescribing what has proved in my hands the most satisfactory of the newer hypnotics. These effects obtain because of the very slow diffusion of the drug when taken in a state of simple suspension, the whole amount not entering the circulation for many hours after its ingestion.

I desire to call attention to a more satisfactory mode of administering sulphonal; a method that occurred to me when having occasion to take the drug a year or more ago, and one which has subsequently afforded me results in practice not in the least obtainable by its use in the common way. My method is as follows: I direct that just before retiring the sulphonal powder be well stirred in a glass two-thirds full of boiling water (about six fluid ounces) until entirely dissolved. The water must be boiling, and to insure that it is at the boiling-point when brought in contact with the sulphonal, it had better be heated on the spot. It can be boiled in a tin-cup over the gas, or over a spirit lamp. After the sulphonal has entered into solution, which will occur in a moment or two if it be well-stirred, cold water may be very cautiously added to reduce the liquid to a drinkable temperature, which, if the patient is accustomed to taking hot fluids, will be one not sufficient to cause the slightest precipitation of the drug; or the hot solution of sulphonal may be permitted to cool to this temperature, the cooling process being facilitated by continued stirring. To insure success the sulphonal must be taken wholly dissolved, and the hotter the solution is the better. It is surprising to one accustomed to prescribing this hypnotic in suspension several hours before bed-time, to allow for what has been called the period of therapeutic incubation, to note the prompt and satisfactory result of this simple manoeuvre. The hot solution dilates the gastric vessels and stimulates them to rapid absorption, so that diffusion takes place from the stomach probably before slight or any precipitation of the drug occurs; entirely unlike the result that follows when the sulphonal

is ingested in a state of simple suspension. In the latter case gastric absorption can scarcely occur, and hours are perhaps consumed before the whole amount taken enters the blood. The period of therapeutic incubation is practically done away with. Sleep results in most cases in a very few moments, and seems to be more profound and dreamless than that from a larger dose taken in the ordinary way, and the annoying condition of drowsiness usually present on the subsequent day is scarcely felt if the dose be properly graduated. The hot solution, which has a slightly unpleasant taste from the dissolved sulphonal, may be rendered decidedly palatable by the addition of a tablespoonful of some such *liqueur* as *crème de menthe* ("green mint"), which, apart from its efficiency in this direction, will probably tend to promote still more rapid absorption of the drug. To obtain an immediate and altogether satisfactory result from this method it is desirable that the stomach be empty or at least comparatively free from food, so that precipitation be not favored and absorption delayed by the entanglement of particles of sulphonal and undigested food, but as it is unnecessary to take the dose until the retiring hour there will usually be no difficulty from this.

KOCH'S TREATMENT: EXPERIMENTS ON CATTLE.—PROFESSOR BOLLINGER, of Munich, gives (*Münch med. Wochenschr.*, January 13, 1891), a summary of some experiments with Koch's fluid made in the Veterinary Institute at Dorpat by W. Gutmann on three tuberculous cows. The disease was diagnosed partly by physical examination, partly by the presence of tubercle bacilli in the bronchial mucus and in the milk, and partly by changes in the lymphatic glands. Relatively large doses were employed, 0.1 g. being injected into one animal, 0.2 g. into a second, and 0.3 g. into a third. The injections were made behind the shoulder-blade. The temperature was taken every hour on the day of the injection and the following day and night. In all three animals the temperature began to rise about eleven hours after the injection. The reaction corresponded to the amount of the remedy exhibited, the maximum attained in the first animal being 40° C., in the second 40.8°, and in the third 41.7°. The duration of the fever in the three cases was four, nine, and ten hours respectively. In the first cow another injection of 0.3 g. was given four days after the first; reaction came on in from eleven to twelve hours and lasted four hours. In all three animals during the febrile period there was some difficulty of breathing and loss of appetite, but the next day they took their food well and rumination was active as usual. No rise of temperature followed the injection of 0.3 g. in two healthy bulls which were used as "control" subjects. Twenty-four

hours after the injection they were slaughtered and all the organs were found to be perfectly normal. Gutmann, therefore, concludes that Koch's remedy is a most valuable aid to diagnosis in the case of cattle suspected of tubercle. In this view Professor Bollinger agrees with him. —*British Medical Journal*.

Surgery.

COMPOUND COMMINATED COMPLICATED FRACTURE OF THE DISTAL EXTREMITY OF FEMUR. RECOVERY WITHOUT AMPUTATION.—The *Montreal Medical Journal*, February, has a brief report of a case of the above named accident reported by DR. JAMES BELL. The patient, male, aged 30, was brought into the hospital with so severe a fracture of the lower third of the thigh, and with so much laceration of the soft parts that amputation was, upon consultation, recommended. To this the patient would not consent, so that conservative surgery was perforce resorted to. Under ether the wound was thoroughly cleansed, several small, loose fragments of bone were removed, which, with a portion of the bone excised, equalled about four inches of the femur-shaft. The articular end had been split and the condyles driven asunder by the violence of the accident; these latter were brought together and pinned with Macewen's pins for the excision of the knee-joint. The patient rallied well after the operation and no troublesome symptoms arose. The temperature at no time exceeded 99.5° F. The patient was discharged at the end of three months and twenty days with a good union and a considerable amount of mobility at the knee-joint, which will, without doubt, be increased by passive exercise, the patient being at an age when this can be insisted upon rigorously and to some purpose. The shortening amounted to three and a half inches. A better result than this is seldom seen either in private or hospital practice, and may serve as a landmark for surgeons who need encouragement in their pursuit of conservative methods.

PAINLESS CIRCUMCISION.—G. W. OVERALL (*Medical Record*) says: For the past fifteen years I have performed circumcision quite frequently for the relief of various nervous disturbances. Since the introduction of cocaine I have used it almost exclusively in men, and frequently in children, by injecting it beneath the integument in the prepuce (having previously placed a rubber band around the penis half an inch or more back of the corona to limit its effect to the prepuce).

The pain attending the introduction of the needle into the sensitive skin has been a serious objection in men, and almost as bad in children, as the operation itself. Then I have had various postponements, and often complete abandonment

of it, because I could not promise "that it would not hurt." Now I can promise an operation where a child would not even know it until it was performed.

I do not want my patient to see the operation, and in the case of a child I conceal the instruments. I then place the patient upon his back and lay a small pillow on his chest so that he cannot see over it. I then adjust the rubber band, take a freshly prepared 30 per cent. solution of cocaine and inject with a small blunt-pointed syringe a few drops into the preputial orifice, at the same time I hold the end of the prepuce with my left hand, to prevent the escape of the fluid. I then press upon the fluid with my right hand to enable it to come in contact with the entire mucous membrane. I hold it for five or six minutes, when the mucous membrane is completely anesthetized. I then introduce carefully my hypodermic needle through the preputial orifice and penetrate the mucous membrane and inject a few drops of cocaine. I then move it to another part and repeat the injection. It necessarily requires caution to prevent puncturing the integument, which would cause pain. I operated upon a child six years old, very small, nervous and excitable, while he was discussing with his mother the kind of toys he would get for Christmas. I also operated upon a boy 14 years old that came from an adjacent town (using silk gut ligature), he did not feel the slightest prick of the needle. He returned home the same evening and recovered without a bad symptom. It is always better to use a ligature that does not require to be removed.

Bacteriology.

THE EFFECT OF KOCH'S REMEDY UPON THE INTERNAL ORGANS.—PROF. VIRCHOW (*Berliner Klinische Wochenschrift*, January 12, 1891), reports the results of autopsies made at the Pathological Institute. Twenty-one of these cases occurred before the close of last year, and six or seven were added to the list previous to his report (January 7). Of the first twenty-one cases phthisical, with the process localized in the lungs, the remaining five were made up of one case of bone and joint tuberculosis, a peculiar case of carcinoma of the pancreas with an old lung complication, one of empyema, one of old rectal fistula, and lastly a case of arachnitis tuberculosa. The visible effects of Koch's remedy show it to be an irritant, producing redness and swelling, which is also present in the internal organs, and frequently in the severest forms. In the case of the tubercular arachnitis, a child from the wards of Prof. Hensch in whom, sixteen hours before death, an injection had been made, showed a greater degree of hyperæmia and injection of the brain and its membranes, than Virchow had ever before observed. He also carefully examined and could

not determine any alteration in the tubercular process. This acute hyperæmia and swelling was frequently observed in other organs. The walls of old cavities were often red, and infiltrated with blood.

A case is described in which death took place from anæmia after severe hæmoptysis. In this case the process was not confined to a simple hyperæmia and swelling, but it was possible to determine an active cell proliferation. This cell proliferation was especially well marked upon the wall of the cavity as well as in the affected bronchial and mesenteric glands. The swelling sometimes takes on a dangerous character, especially in the throat, where it may cause phlegmonous tonsillitis or pharyngitis, or erysipelatous œdema of the glottis. It is difficult to say whether this inflammation is caused by the injection or not. The changes in the lungs are divided into two classes—the first presenting the common picture of caseous pneumonia. Prof. Virchow did not remember to have seen in years so extraordinary a case of caseous hepatization as was presented in one of the specimens shown. The lung appeared like a blood sausage, with here and there pieces of pork distributed through it. In this case six injections were employed, the last one four weeks before death, the treatment having been discontinued when the pneumonic process appeared. Pneumonia in phthisis commonly presents itself in three forms, the fibrinous, caseous and catarrhal. The fibrinous was not observed in any of the cases. Eleven of the cases closely resembled the catarrhal, and yet there were marked differences. The exudate was cloudy, gelatinous, resembling the caseous but without its character; frequent vacuoles were seen, with a tendency to coalesce, a similar appearance to that presented in gangrenous pneumonia.

DEATH FROM KOCH'S LYMPH.—PROF. GRASSET, of the Hôpital Saint Eloi (*La Semaine Médicale*, January 21), reports the death of a young man following the lymph injection. The patient presented the signs of a circumscribed pleuropulmonary tuberculosis situated in the upper portion of the right lung, that was not accompanied by fever. The injection produced a rapid change for the worse, with the formation of large cavities, and the rapid extension of the tubercular process through the same lung and to its fellow. A careful description of the autopsy is given with an account of some pulmonary lesions that they attribute to the lymph, among others the "injection pneumonia of Virchow."

The writers conclude that the lymph converted an apyretic circumscribed tuberculosis into a case of "galloping phthisis," with severe hæmorrhage and high temperature. The patient died ten days after the injection.

SATURDAY, FEBRUARY 21, 1891.

THE REPORT ON MEDICAL EDUCATION.

The seventh Report on Medical Education of the Illinois State Board of Health, just received, is the most complete work of its kind that has ever been issued by the Board. It includes not only all the medical colleges in the United States and Canada, as heretofore, but a summary of the requirements in foreign countries as to preliminary education, a list of the teaching institutions and their requirements in all foreign countries, and the regulations in these countries as regards the license to practice.

It is evident from the report that there is an upward movement in higher medical education, and it gives to the Chicago Medical College the credit for having taken the first step in this country for the three years' graded course—in 1868. It was not until 1881, however, that there was a decided movement in this matter. In this year the Illinois State Board of Health first classified the medical colleges of the United States and Canada in a Report on Medical Education. One year before this the Board had adopted its schedule of minimum requirements, to go into effect after the session of 1882-83. Since 1882 the movement for higher medical education has acquired more and more momentum, as will be seen from some figures taken from the Report. In 1882 there were but 43 colleges requiring certain educational qualifications for matriculation; in 1886 there were 114; in 1889, 117; in 1890, 124; and now there are 129. In 1882 the number of colleges requiring attendance on three or more

courses of lectures before graduation was 22; 41 in 1886; 47 in 1889; 64 in 1890; and 85 at present. Since 1880 the length of the lecture terms has been increased from an average of 23.5 to 26.3 weeks. In 1882-83 there were eight colleges that had lecture terms of but sixteen weeks. In 1882-83 only 42 colleges had terms of six months or more; in 1883-84 the number was 49; in 1889-90 it was 76; now it is 111.

One of the very suggestive features of the Report is a table showing the results of the examinations by the medical examining boards of Alabama, Minnesota, New Jersey, North Carolina, South Carolina and Virginia. Of the institutions represented before these boards 77 are in the United States, 5 in Canada, and 12 are foreign. Our 77 colleges were represented by 1,183 candidates, graduates, of whom 895 passed and 288 failed to pass. It is noteworthy that there is a great difference in the percentage of rejections before the different boards. Excluding the results before the New Jersey Board, which examined only 11 candidates, the Alabama Board rejected 7.84 per cent., the Minnesota Board 29.81, the North Carolina Board 20.61, and the South Carolina and Virginia Boards 28.82 and 29.51 per cent., respectively. The variation is not so great, however, as in the case of the nine Prussian examination commissions in 1890, the extreme limits of rejections before these commissions being 9.3 and 41.03 per cent. It is suggested in the Report that the several State boards hold a meeting for consultation and that they adopt some plan by which examination papers may be exchanged, since it is important that the work of these boards should be as uniform as possible.

Two tables show the marks of the candidates rejected by the Virginia Board in September, 1890, and of the candidates that passed the New Jersey Board in October, 1890. It is a somewhat remarkable fact that a non-graduate received the highest mark of any candidate rejected by the Virginia Board. The names of the colleges from which these candidates were graduated are given. It is suggested that each board of examiners prepare a table of this kind at each examination, since the publication of such statistics will undoubtedly have a powerful effect on colleges. The lowest marks received by the rejected candidates were in chemistry, anatomy and

surgery. Before the New Jersey Board the lowest average (by successful candidates) was in surgery and surgical anatomy.

The Report calls attention to the value and increasing number of courses preparatory to the study of medicine, now offered by some of the largest universities in the country. There is undoubtedly a tendency towards beginning the education for the work of life earlier, and it is now more than ever recognized that the foundation for a proper study of medicine should be laid before the student actually begins to study medicine.

The Report is earnestly commended to the careful attention of all the colleges, as well as to all interested in higher medical education. It shows that there is no longer any doubt that four years of medical study and three courses of lectures is to be the rule in this country until a still higher standard is adopted. Some of the colleges have arrayed themselves against the higher standard. It is evident they must accept it or join the long roll of extinct medical colleges.

THE SUPPRESSION OF SYPHILIS.

It will be of no small interest to our philanthropists—and there are not a few in the ranks of our profession, be it said to our credit—to learn that the outcome of measures put forth of late years on the continent of Europe, with regard to the regulation of prostitution, have proved unavailing, from both a moral and sanitary point of view.

Morally, the effort to regulate—and thereby, in a measure, stop—the vice of prostitution, has only resulted in a more than compensating clandestine recourse, which appears more penetrating in its effects, and evil in its consequences, than maintained previously. And through this result, and in the aversion of the syphilitics in the regulated houses to being hospitalized for long time as such, it is believed that a wider dissemination has been given to this poison.

So thoroughly convinced upon this point is a recent writer to the *Westminster Review* that his one conclusion is this:

As a means of lessening the amount of the diseases associated with the practice of prostitution, the system of legal recognition, toleration, and regulation, always has proved and always must prove a complete failure.

This only tends the more to illustrate that law

cannot answer for enlightenment; that progress in the direction of moral and physical elevation of the race must ever depend upon a proper and widely-extended teaching. If ignorance of danger does not immediately lead to syphilitic infection in all or many cases, then that carelessness and animalism born where ignorance and sin prevail is accountable for all the other factor fails to cover.

Such training as will in the best manner open to the mind of "budding" youth the principles of sexual hygiene will no doubt prove—when it becomes sufficiently recognized—the most successful means of combating, not only this, but kindred influences of a widely-evil nature.

PROPHYLAXIS.

As a means of markedly invigorating the entire organism, and rendering thereby the system less prone to the influence of all external disease-producing agencies, an English physician reports, in a recent number of the *British Medical Journal*, the benefits of a daily morning cold bath. The bath used is *cold*. Often the ice has to be broken before the bath can be taken. Then the skin is toweled thoroughly. This physician says he never has a "cold;" never wears an overcoat—whatever the weather may be; has had no illness for many years; and would as soon think of stopping his meals, as to drop off the customary cold "tubbing."

In this connection might be mentioned the still more radical system of FATHER KNEIPP, the village priest of Voerishofen, Bavaria. It is said that he is well-regarded by the medical profession, and that many doctors go to him to learn his method of cure and care. The features of this so-called method are not at all new of themselves, and it is more the combination of requirements, together with the rigidity of procedure, which commands attention.

FATHER KNEIPP is simply a health reformer, and as such he declares strongly against all woolen garments next the skin. The under-clothing he recommends is made of strong, coarse linen. Next of his requirements is the cold bath, which is to be taken quickly, and without subsequent drying of the skin. The linen garments are to be put on at once, while the moisture of the bath is still upon the body.

Then comes the practice of walking or running barefooted in wet grass in cold weather, or in freshly-fallen snow. The village of Voerishofen lies in a valley where green meadows abound, and is therefore particularly adapted to this form of exercise. After running in the wet in this fashion the patient puts on coarse linen socks, and boots, and walks briskly for a spell. Then as to internal attention tea and coffee are absolutely prohibited, and animal food is discouraged. Bread, fruit, vegetables and milk are the substances permitted. "There are few better meals," says this man, "than plenty of fresh fruit and a piece of bread."

The patients are advised to drink before eating, never while eating, and after eating only when it seems necessary; and then moderately. Hard beds; cool, well-ventilated rooms; and the use of good things—without their *abuse*—quite completes this hygienic plan.

UNNA'S PASTES AND PASTE-STICKS.

LASCAR has contributed an article to the *Pharmaceutical Record*, January 5, giving the results of a vast number of trials with all the ointment bases, new and old, especially with the gelatine ointments and pastes of UNNA. Many of the latter have as their base anylum and gum arabic, and UNNA has found it serviceable to bring such pastes to a consistency so that they can be formed into sticks, and he is in the habit of incorporating in them a variety of medicaments, as iodoform 40 per cent., salicylic acid 10 to 40 per cent., resorcin the same, corrosive sublimate 5 to 10 per cent., oxide of sulpho-carbolate of zinc 20 per cent., or pyrogallie acid 40 per cent. These paste sticks require to be moistened when applied to the skin. They are not to be confounded with the salve-sticks which resemble the well-known cosmetic sticks of French origination. Their consistency, however, is about the same as that of the ordinary cosmetic stick, and their base is spermaceti or wax with olive oil. The paraffine oils are not suitable for these purposes.

One word in regard to the gelatine unguents of UNNA may be added here from the observations of LASCAR. Being an entire novelty to him, he encountered no little difficulty in obtaining a superior article. He used the Cox gelatine and macerated it with cold water until it swelled,

then heated it in the water-bath and added 10 per cent. of glycerine, then added a concentrated warm solution of Russian isinglass, in the proportion of 1 to 4 of the gelatine, the product being a glyce-ro gelatine that dried more quickly than any other combination experimented with by him, and that left a firmer coating on the skin when applied directly thereon.

DOCTORS AND ADVERTISING.

The *London Daily News*, in an article with the above caption, puts in a special plea "regarding the severity of the unwritten law of professional etiquette." It claims that medical men "are constantly under suspicion of advertising themselves when they are really doing nothing of the sort." "If the committee of the local literary and scientific institute," says our secular brother, "will print the name of 'Dr. Abernethy Astley Cooper Jones' in big type, with a whole row of initials after it, is it fair to make him responsible for that?" Aye, there's the rub! Were the capitals, as we suppose them to have been, the measure of self-conceit, or only the expansion of the manager's admiration? Or did they act as a bait for the public, pretty much as "The biggest show on earth?" We do these things much better in America. We are careful never to submerge self in profession, college, hospital or association. Happily, too, we are more ingenious in our methods and have a much wider choice, such as the carefully written interview, with its patronizing tone and convenient avenues of escape; the society item, with one's diamond bedecked wife and stunning equipage; the summer movement to secure a much-needed rest; the fag-end of "Among the distinguished persons present we noticed;" the summons from a distance or an enormous fee; a gratuitous diagnosis, broadcast among the laity; and last of all, for even the humblest brother we have provided the anecdote and the lugubrious office of pall-bearer.

A medical correspondent of *The Lancet*, quotes the *News*, confesses to finding "intense pleasure and relaxation in addressing an intelligent audience," but he had to endure "the darts of slander." Is it possible that "the intelligent audience" can have no redress in a damage suit? But oh, men of many talents! these are the struggles of genius, and we need not multiply exam-

ples. Perhaps your wares are no better than your customers. Wise men of the East, know ye not that there is a way to sail under false colors, notwithstanding your incorruptible newspapers, your immaculate municipalities, and your poor but honest street-sweepers? Many know the route, and many have returned safely to a haven of comfortable competence.

A friend of this luminous man of "intelligent audience" proclivities, "can make ten guineas by one evening address, and earn as much in an hour and a half as his detractors can do in a week, but owing to the intolerable priggish attitude of his fellow practitioners, he is obliged even to cease his gratuitous efforts on behalf of the churches, chapels and local charities." We hope, persecuted man that he evidently is, that he has never bored his hearers or made them a means of improvement in oratory. Demosthenes may have been (still, we do not know), more considerate in betaking himself to the sea-shore. However, despite the temptation, we shall spare him our Western story of "poor pay and poor preach."

Briefly and seriously, in regard to the whole matter, let us state that these "reading notices" which we have in mind are costly, sometimes profitable and not infrequently disastrous. To the adventurer and charlatan there may be a necessity for elbowing, but society in the one case has furnished him with the crowd, and the profession in the other has begotten for him the confidence. To our weak brother we can only say that medicine as a vocation, being personal in its limitations, cannot be over-lucrative. Rather say in its proper column what you desire without fear of the blue pencil, and take your place among the other honest tradesmen.

LARGE BILIARY CALCULUS DISCHARGED THROUGH AN UMBILICAL FISTULA.

In the *New York Medical Journal*, January 31, DR. COLEGROVE reports the passage of an extraordinarily large biliary calculus by the way of an umbilical fistula. A lady, aged 83, had an abscess around the umbilicus, attended with a great amount of disturbance, pain, loss of sleep and appetite; it communicated externally by means of a fistula, through which pus was discharged for a week or more. One night she was suddenly taken with an increase of the pain, so intense that she be-

came collapsed; with this there was the extrusion, through the umbilical fistula, of a calculus measuring four inches in circumference. Two months later the fistula had healed and there was a complete absence of local tenderness, and the patient was restored to her former measure of health.

EDITORIAL NOTES.

THE OFFICE OF CORONER.—The *London Law Journal*, "referring to the approaching abolition of the office of coroner throughout the United States," says: "The coroner's inquest in an average American State seems to have been simply a costly and tedious way of doing nothing; the verdict of the jury was not only not conclusive, it was not even evidence, and the subsequent trial proceeded without any reference to it whatsoever." All this is written in the past tense, as of an accomplished fact, and without the theory of the preliminaries of an indictment. Meanwhile the Massachusetts experiment of medical examiners works admirably, and has stimulated reformatory discussions in our well populated communities.

It is pertinent to allude in this connection to the usage of most European nations, which is to commit "the sudden death inquiries" to the public prosecutors, with the option of medical aid. Here, as everywhere in the civilized world, the certificate, barring suspicions of crime or the fixation of responsibility, is held to be final. The ruling of the law appears to be that an opinion, however erroneous, cannot be a misdemeanor even in the mildest sense of the term. Were this otherwise, but few articles on medical education would need to be written, since none would be rash or Quixotic enough to court an unnecessary doom.

THE WORLD'S CONGRESS AUXILIARY OF THE WORLD'S COLUMBIAN EXPOSITION.—Extensive preparations for International Congresses during the Exposition are being made by the World's Congress Auxiliary of the World's Columbian Exposition. The officers of the Auxiliary are Charles C. Bonney, President; Thos. B. Bryan, Vice-President; Lyman J. Gage, Treasurer; Benjamin Butterworth, Secretary. These officers have been working three months on the subject in hand, and have presented to the directory a report showing that they had enlisted the sympathy

and coöperation of distinguished men in politics, science, religion, education, moral and social reforms, literature, law, and the artistic and learned professions. The work outlined is on the broadest scale, and congresses of the representatives of all the branches indicated have been provided for. It is the intention to bring to Chicago not merely a few distinguished people, but a large number of cultivated and intelligent persons from all parts of the world. Much difficulty, the report says, was experienced in the work of forming a list of standing committees and assigning and specifying their work. The standing committee on Medical and Surgical Congresses, including Dentistry, Pharmacy, Public Health, and Private Sanitation, with a special committee for each organization of this class—Dr. N. S. Davis, Dr. H. A. Johnson, Dr. H. M. Lyman, Dr. J. S. Mitchell, Dr. R. Ludlam, Dr. R. N. Foster, Prof. Oscar Oldberg, and Benjamin Butterworth, Secretary.

ARMY MEDICAL EXAMINATION.—Surgeon-General Sutherland, of the U. S. A., has issued the following notice:

An Army Medical Board will be in session in New York City during April, 1891, for the examination of candidates for appointment in the Medical Corps of the United States Army, to fill existing vacancies.

Persons desiring to present themselves for examination by the Board will make application to the Secretary of War, before April 1, 1891, for the necessary invitation, stating the date and place of birth, the place and State of permanent residence, the fact of American citizenship, the name of the medical college from whence they were graduated, and a record of service in hospital, if any, from the authorities thereof. The application should be accompanied by certificates based on personal knowledge, from at least two physicians of repute, as to professional standing, character, and moral habits. The candidate must be between 21 and 25 years of age, and a graduate from a regular medical college, as evidence of which, his diploma must be submitted to the Board.

Further information regarding the examinations may be obtained by addressing the Surgeon-General U. S. Army, Washington, D. C.

NICARAUGUA CANAL HOSPITAL AT GREYTOWN.—A hospital has been organized at Greytown, having 125 beds. It has its regular staff of surgeons, apothecary, trained nurses and hospital steward. Its roof and sides are constructed of corrugated iron with a view of minimizing the dangers by fire and febrile infection. Every suitable modern hospital appliance has been requisi-

tioned and supplied. Subsidiary hospital stations have been established up in the interior at two points where large bodies of canal workmen are employed. These have an assistant surgeon and druggist at each.

REMOVAL.—We regret to learn that by reason of the ill health of his family Dr. James A. Lydston, late Chief of Eye and Ear Department of the Pension Bureau, Washington, D. C., has been obliged to relinquish the Professorship of Chemistry in the Chicago College of Physicians and Surgeons. He will resume the practice of his specialty in Denver, Colo.

LONGEVITY IN THE SOCIETY OF FRIENDS, ENGLAND.—A recent report of the vital statistics of this Society in the United Kingdom is commented upon in *The Lancet*, January 3. The membership of this body is stated at 15,500, and the mortality during the past three years is given at an average of 256 deaths per annum, or about 16.5 per 1,000. A remarkable feature of this mortality is the high age of the deceased: of the 769 persons dying in three years, 480 or 61 per cent. were 60 years old or upwards. Another noteworthy point is the small mortality among young children. In the year 1889, there were only fifteen deaths of children under 5 years of age. This statement may be taken to show the abnormally low rate of mortality, but in the absence of statistics showing the number of persons living in the various age periods, it may also be taken to show—that which is probably the true state of the case—an abnormally small number of young children in the Society. The *Lancet* very properly points out the desirability of making such future reports more instructive by a statistical division by periods of age of the 15,500 members, so many of whom are given to lives of peace, sobriety and good works.

THE MEDICAL SOCIETY OF THE MISSOURI VALLEY.—The next meeting of this Society will convene at Omaha, Neb., March 17, at 7:30 P.M. It has an enrollment of about 300 members. The Secretary, Dr. F. S. Thomas, of Council Bluffs, Ia., will be pleased to communicate with those who propose to present papers at that meeting.

PROFESSOR PFUHL. Professor Koch's son-in-law, is to have charge of the new institute for experimental medicine in St. Petersburg.

TOPICS OF THE WEEK.

THE PROGRESS OF SURGERY IN 1890.

In the last year there has possibly been a slight lull in the cumulation of surgical discoveries, and yet we are unable to look back upon the progress of the year that has just expired without feeling that there is ample ground for congratulations to the medical profession upon the strides that have been made.

The great event of the year was the Medical Congress at Berlin, where the large attendance of men most prominent in our art and science, from all parts of the civilized world, brought together a wealth of facts and views that are now crystalizing into a valuable mass of information.

There has been noticed in the year gone by that reaction which was bound to follow the enthusiastic prevalence of intra-abdominal operations during the last few years. The matchless skill of the leaders in these procedures has taught us a technique that can scarcely be improved upon; while the number of operations performed has become less, through more perfect discrimination in the selection of cases absolutely requiring such measures. In the matter of operations for the relief of disorders due to inflammatory conditions of the vermiform appendix, the main points developed have been chiefly in the line of improved diagnosis, and in a general belief in the advisability of early interference.

The study of intestinal anastomosis first evolved by Senn has been taken up by a host of men, though, strange to say, its practical applications are still limited too much to our own country. The monograph written by Professor Senn upon the subject of the Diagnosis and Operative Treatment of Gunshot Wounds of the Stomach and Intestines, bids fair to become one of the classics of surgery for years to come. No better illustration of the progress made in this domain of surgery can be given than the brilliant results obtained by Professor Bernays in a series of seven cases of gunshot wounds of the abdomen, which formerly would have been regarded as hopeless and left to die without surgical interference.

The methods of skin grafting and transplantation devised by Thiersch have proven their value in many hands during the past year, and now are fully admitted among the established surgical procedures of common occurrence.

Mr. Horsley's experiments in the transplantation of the thyroid gland of animals to the human subject have been followed by a practical application of the procedure, and bid fair to add one more to the many splendid results attained by this indefatigable experimenter.

In the surgery of the joints a more conservative tendency is becoming manifest; and in Germany, especially, the injection of iodoform emulsions in tuberculous joints has been employed with much success as a substitute for more radical procedures.

Among the improvements brought about in the technique of special operative procedures, the bloodless method of amputation at the hip joint, devised by Professor Wyeth, of New York, and performed with success by himself and others, takes high rank.

Operations upon the nerve-centres and the nerves themselves have greatly multiplied, and operations of un-heard-of magnitude have this year been reported, by which the brain and cord have become a far wider operative field than had ever been previously thought possible.

The discovery with which Koch startled the medical world a few months since has not been sufficiently developed to permit of positive deductions regarding its value in the various forms of surgical tuberculosis, although from present indications it will supersede all other methods for the treatment of lupus.

Such are a few of the results of the past year, and, in this marvellous age of progress, we are left to wonder at what we may have to chronicle for another year, though we are conscious that the last one has marked a decided era of improvement in our methods and knowledge.—*International Journal of Surgery.*

ANOMALIES OF BRAIN AND SKULL IN CRIMINALS.

Professor M. Benedikt having commenced to study anthropologically the "great criminals" of Vienna, has communicated some results of his examination of the brain and skull of Hugo Schenk, a notorious murderer of women, to the *Wiener medizinische Blätter*, January 1, 1891. The brain presents much that is interesting. In each hemisphere the internal parieto-occipital fissure shows no direct adjunction to a common stem with the calcarine, but enters the latter by an irregular lateral offset. The calcarine sulcus communicates with the fissure (termed "limbic" by the author) separating the gyrus hippocampi from the temporal convolutions. This limbic sulcus further joins the collateral, and by its rectilinear form evidences aplasia of the gyrus hippocampi, as has frequently been observed in epileptics. The separation of the gyrus hippocampi from the lobulus lingualis by a fissure, instead of conjunction by a wide bridge, is entirely opposed to the type of gyrencephalous animals and of normal man; it always points to a great disturbance in the balance of the constructive force. The confluence of the calcarine fissure with the limbic must also be regarded as a stigma of high grade. On the mesial surface of the left hemisphere aplasia of the quadrate lobule is noticeable through operculation. On the right hemisphere a branch of the collateral fissure courses around the lower outer margin and joins the first temporal sulcus. On the outer surface of this hemisphere the anterior central and the angular are the best developed gyri. The outer aspect of the left hemisphere reveals arrested growth of the frontal lobe, with high development of the two central gyri. A double connection of the central fissure with the first frontal sulcus insulates the lower part of the upper half of the anterior central convolution. The parietal lobe and two external annectants are markedly hypoplastic. In strong contrast therewith is the bulky development of the occipital lobe and adjacent parts of the second temporal convolution. This very unequal development of the various brain segments indicates defective cerebral equilibrium. Taking into account the extraordinary development of the sexual

passion in this murderer, it was specially interesting to discover what parts of the brain showed a preponderance of growth, and to consider whether those parts could be associated with the cortical sexual life. In this case it would appear that the most important seat of the cortical sexual existence is in the left occipito-temporal lobe. The cranium bears as strong evidence of degeneracy as the brain; it is grossly asymmetric—the right fronto-parietal and fronto-temporal and left occipito-parietal and occipito-temporal regions being prominent, and the whole base of the occiput, particularly on the left side, bulging downwards. Internally and externally the cranial sutures are almost obliterated.—*British Medical Journal*.

THE LEGAL VIEW OF INSANITY COMMITMENTS.

Judge David McAdam, the President of the Society of Medical Jurisprudence (New York), in a recent discussion said that the law relative to commitments of insane persons was not generally understood. He would venture the assertion that of the 17,000 persons now in custody in New York State on charges of insanity not more than 1,000 had been committed according to process of law. He declared that a certificate signed by two physicians and attested by a judge did not constitute a process of law. Before a person could be legally deprived of his liberty he was entitled to a hearing, a trial before a jury, and an adjudication of his case.

The common law defined what should be done in such cases. The statute law merely defined certain things that should not be done. A magistrate's indorsement on a certificate of insanity signed by two doctors simply attested the respectable standing. His signature added no force to the commitment, and should a person thus committed prove to be sane, he or she would have a good cause of action against the doctors for perjury, conspiracy, and civil damages.

BEER-DRINKING EXTRAORDINARY

Beer-drinking amongst students in Germany and other Continental countries is proverbial, and we may say that the average Englishman is a beer-drinker if not a teetotaler. In Ireland and Scotland alcohol in the form of spirits is the chief beverage. In the prosperous times of 1873 and 1874 in this country, the working collier was said to have forsaken his beer and taken to drinking champagne, but the ensuing depression soon put an end to this. Now, however, with a return of prosperity in the coal trade, we find his beer-drinking propensities developing. An extraordinary state of matters was proved to have taken place at Ince, near Wigan (during an inquiry by Mr. Brighouse, the county coroner, into the death of a man who had been drowned in the Leeds and Liverpool canal). A comrade of the deceased stated that he had seen him the previous afternoon, and up to that time he might have had a dozen pints of beer (six quarts). At night they had two glasses, and afterwards four small glasses of whisky. It was further shown that in the course of the afternoon and evening the deceased and another man had a wager as to who could drink three pints of beer in the shortest time, and that he drank

these three pints in under five minutes' time—in fact, in half the time it took the other man. No wonder this man, when he started to go home, lost his way in the darkness and fog, and that when he fell into the canal he was unable to help himself out. The beer drunk by the Germans and Bavarians is a much lighter beverage, and therefore probably contains less alcohol. Could not the British brewer concoct a beverage which would be less intoxicating? It is a popular notion that no harm can result from the use of beer, that delirium *a potu* never follows its employment. But this is a delusion; gastric and hepatic derangements are common from its abuse, and in the cases of continuous beer-drinkers, such as beer-sellers and draymen, delirium tremens is not unknown.—*Lancet*.

THE PAUPER INSANE OF NEW YORK STATE.

The bill before the legislative bodies of New York, appropriating the necessary money for carrying into effect the law passed last year making the pauper insane a State charge, has probably at the present writing become a law. For a wonder, party lines and selfish schemes have been inoperative. When New York decided last year to remove the insane from the poorhouses and place them in State asylums she ought to have provided the funds for making the transfer. But reforms move slowly. Those who had charge of the bill of 1890 felt that they had done the best they could in securing its passage without the means to make it effective. This year they have introduced the supplemental measure. The appropriation asked for is a modest one, while the amount of good which it will conserve can hardly be over-estimated.

A MEMORIAL TO PIROGOFF.

During the Congress of Russian Medical Men recently held at Moscow, a sketch of the proposed memorial by the Russian Academician, Mr. Sherwood, was exhibited in the hall of the University. The great surgeon is represented as seated on a chair, with a skull in his hand and an open book at his feet. The sides of the pedestal are adorned with crowns of laurel, and on the front of it is the inscription in Russian, "To Nicolai Iwanowitsch Pirogoff, the Thinker-Surgeon. 1810-1881."

LEPROSY IN RUSSIA.

The municipal authorities of Riga are about to erect a leper-house at a distance of from six to seven versts from that city, at an estimated cost of 55,800 roubles. This includes a house for the medical superintendent and one for the warden, besides a post-mortem room, etc. Although the number of lepers in Riga and its neighborhood amounts to about 100, the new lazaretto will contain only 40 beds. As isolation is not compulsory, it is thought likely that accommodation thus provided will be sufficient for the lepers who voluntarily seek admission. It is expected that a hospital for lepers, with accommodation for 40 or 50 patients, will be opened some time in the spring, at Neunal, a place about 70 versts from Dorpat. A branch institution, with 10 or 15 beds, will also be established in the immediate neighborhood of that city, which will serve the purpose of a receiving house for the hospital at Neunal.

ARREST OF WHOOPING COUGH BY MANIPULATION OF HYOID BONE.

Naegely in *La Semaine Médicale* September 3, reports on a new manipulative method of arresting the paroxysms of whooping cough and of relieving neuralgia of the fifth nerve. Over fifty patients have been treated successfully by the following procedure: the operator stands in front of the patient and with his thumbs elevates the greater cornua of the hyoid bone, a purchase for the index fingers being obtained by resting them behind and above the ears of the patient; the other fingers rest upon the neck. Relief having followed the use of this method in a number of cases of pertussis, Naegely next applied it, with very general success, in a number of other cases of nervous disorders, such as neuralgia of the fifth nerve, migraine, globus hystericus and nausea of nervous origin. According to his experiments, a single application of elevation of the hyoid and larynx, maintaining them in that position for a minute to a minute and a half, has frequently sufficed to remove the pain or distress completely but, in some cases the procedure has had to be repeated several times. The scientific explanation of such results as these is not very tangible; but Naegely inclines to the opinion that those results depend upon one of those phenomena of inhibition, so well formulated by Brown-Séquard, but the exact mechanism of which remains to be determined.

NIGHT TERRORS SUCCESSFULLY TREATED BY BELLADONNA.

Dr. Lorenzo Hale, of the *Albany Medical Annals*, writes in its December issue regarding the

epileptiform nature of the night terrors of children. A certain proportion of these cases are beyond question an evidence of nocturnal *petil mal*, and those are the cases in which diurnal epilepsy ultimately supervenes. It was in this view that Trousseau's method of treatment by the administration of belladonna in epilepsy was tried in a severe and protracted case of night terrors. Various other means had been tried and had failed, when there were given the patient, a boy of 4 years, five drops of the tincture of belladonna at night. The dose was increased one drop each night until ninety drops were given at one time. The father of the patient was instructed to be careful and exact, and he was faithful and persistent. The results were most satisfactory; not one severe attack of the terrors was experienced after the beginning of the treatment. The severity of the attacks gradually diminished; when no symptoms whatever of the nervous trouble had appeared for more than two months, the dose was decreased ten drops each night. The relief was almost immediate, and there has never since been any recurrence of the trouble. The general final history of all such cases is less favorable, ending as they so often do in epilepsy proper, preceded by a lack of vivacity or a transitory beclouding of the intellect during the day as the disease extends from the night to the daytime.

INFANTILE DIARRHŒA.

- R. Ferri. sulph.,
Sod. salicyl., āā, gr. x.
Glycerini, ʒij.
Aq. dest., ʒjss. ʒ.

Sig. A teaspoonful every one, two, or three hours.

—*Canada Lancet.*

HEMORRHOIDS.

The following is suggested in the *Medical Mirror* as an excellent salve:

- R. Cocain. muriat., gr. xx.
Morphine sulph., gr. v.
Atropine sulph., gr. iv.
Acid. tannic. pulv., gr. xx.
Vaseline, ʒj.
Olei rosæ, q. s. ʒ.

Sig. Apply after each evacuation. Contents of bowels must be kept soluble.

SEMINAL EMISSIONS.

As a direct means of diminishing the frequency of nocturnal emissions, Bumstead recommends:

- R. Potassi bromidi, ʒj.
Tr. ferri chlor., ʒj.
Aque pur., ʒij. ʒ.

Sig. One or two teaspoonfuls in water an hour after meals and at bed-time.

FOREIGN CORRESPONDENCE.

LETTER FROM PARIS.

(FROM OUR OWN CORRESPONDENT.)

Koch's Treatment of Tuberculosis—The late Dr. Baillarger—A French Rejoinder to the Edmunds Bill—Another Cure for Consumption—Death of Baron Haussmann—An Important Legal Pronouncement—Is Cocaine, employed as a Local Anesthetic, Dangerous?

In this medical centre, as elsewhere, the new remedy for tuberculosis has been, and is being, extensively studied at the various hospitals. In a series of admirable lectures, Professor Cornil has given a faithful account of the results of inoculations on his own patients of the Laënnec Hospital. These results do not differ materially from those recorded by other observers, if we except the occurrence of albuminuria in certain instances. The dose did not generally exceed 1 milligram, and this commendable caution has been imitated by most operators in Paris. At the St. Louis Hospital a committee of physicians and surgeons has been appointed to report on the effect of the lymph on the various forms of tuberculosis, and their report will soon be forthcoming. So far as one can gather from the opinions expressed by those most competent to judge, the lymph, however marvelous its diagnostic properties in a large proportion of cases, and however great the amelioration produced by it in lupus may be, has not hitherto fulfilled, as a curative agent, the expectations raised at its *début*. A leading article in the *Paris Médical* of January 10 bears this significant title: "Résurrection du tubage du Larynx. Enterrement des injections de la lymphé de Koch." The writer recalls the successful resuscitation by O'Dwyer of an idea emanating originally from a Frenchman thirty-two years ago, and prophesies that thirty-two years hence Koch's treatment will, on the contrary, have passed into the limbo of things forgotten. The writer avers, on Debove's authority, that in fourteen indubitable cases of tuberculosis,¹ the lymph failed to provoke any reaction whatever. He, finally, adduces as a reason for the renunciation of the method the fact that, while the remedy has failed to cure a single case, it has already caused the death of more than twenty patients: seventeen in Germany, four in Austria, one in Paris and one in Brussels—one fatality occurring in a case of lupus.

M. Léon Petit (Soc. de Méd. Pratique, December 18, 1890) gives it as his opinion that Koch's lymph should be relegated to the laboratory until its range of action can be properly verified. Having, in collaboration with MM. Cérémonie and Gautrelet, found by analysis that the active prin-

ciple of Koch's liquid is an amine, he has succeeded in fabricating a lymph possessing identical properties. This product he has denominated "*la lymphé Française*," and he promises, when the results of experiments now in course of execution on tuberculous and normal animals of different species shall have been rigidly checked and controlled, that he will publish the mode of preparation of this new product.

The eminent alienist, Dr. Baillarger, died on the last day of 1890, at the ripe age of 82. One of the last survivors of the pupils of the famous Esquirol, whose interne he was at Charenton, he was for a long period physician to the Salpêtrière Hospital, and had attained to the crowning dignity of President of the Academy of Medicine. To his indefatigable industry we owe a great number of works on mental medicine which have become classical. These have recently been collected into two volumes, and they cover pretty nearly the whole range of the various manifestations of mental derangement. Melancholia with stupor, *folie à double forme*, hallucinations, general paralysis, the unfolding of the brain in mental development, the normal structure of the cortex, cretinism—these are a few of the subjects treated and elucidated by him in a masterly manner. His obsequies took place on January 4, in the presence of the newly elected President of the Academy of Medicine (Professor Tarnier), and a large gathering of representative men.

In a leader in the *Gazette Hebdomadaire* of January 10, M. Lereboullet calls attention to the warning issued by Professor Grandeanu, Director of the Eastern Agronomic Station, on the danger attending the importation into France of American meat, and with it, of actinomycosis. It is stated that the supervision exercised at Chicago is totally inadequate, as two inspectors are responsible for the examination of an average of 10,000 oxen and 20,000 pigs a day. The Edmunds Bill conferring on the President plenary retaliatory powers on foreign nations whose traders export into the States articles intended for human consumption found to be adulterated, M. Lereboullet hopes that France will not, in her turn, be behindhand in instituting like measures to protect her citizens against the introduction of actinomycosis.

The *éclat* attending the appearance of Koch's liquid in the therapeutical arena has not failed to stimulate the inventive faculties of would-be emulators of the learned Teuton. Some two months ago, the lay press, headed by the widely read *Petit Journal*, heralded, with a flourish of trumpets, the discovery by a hitherto unknown French practitioner named Mathieu, of the obscure village of Estissac, of an infallible cure for pulmonary consumption. The remedy was said to consist mainly of a kind of electricity generated by plants. The happy discoverer, finding Estissac

¹ Observed by Rémond at Berlin.

too narrow a field for the display of his energies, has migrated to Paris, where he has founded a clinique. He is said to be now earning 2,000 francs a day! Unlike Koch, he makes no secret of the composition of his remedy; anyone may read it in the *Annales d'électro dosimètre*. Here it is!

Formula No. 5 de M. Mathieu pour la tuberculose:

Electricité verte, 30 globules.
Pectoral¹, 30 globules.
P², 20 globules.
P³, 10 globules.
C^{1,2,3}, 10 globules.
Fébrifuge^{1,2}, 5 globules.
A¹, A², 5 globules.
Vermifuge^{1,2}, 5 globules.
S¹ S², 5 globules.

The nature of the ingredients of this somewhat cabalistic remedy will, doubtless, prove a puzzle to your readers, but that does not, it appears, prevent M. Mathieu having hosts of adherents among the public of "la ville lumière."

If the late Emperor, Napoleon III, was not uniformly happy in his choice of instruments to carry out his will, no sanitarian will accuse him of having committed a mistake in selecting Baron Haussmann as Prefect of the Seine. Every one knows how this much-reviled functionary "haussmanized" Paris, creating, with an audacity we must all admire, new broad boulevards, uprooting rookeries and foul dens into which pure air never penetrated, and transforming Paris into the airy, well-lighted capital that now ranks second in Europe in point of health. This modest sanitary reformer has just died at the advanced age of 92. It says much for his integrity that, since his retirement in 1870, he had subsisted on a paltry pension of less than \$1,500 a year. His autobiography appeared recently. Being a Protestant, he was interred at the Church of the Redemption, in the rue Chauchat, with military honors.

Charlatanism of the good old-fashioned type is exceedingly rife in certain country districts in France, and many of these irregular practitioners attain to a degree of popularity the practical demonstration of which may, as in the following instance, lead their admirers into serious trouble. In the month of March, 1890, Jean Sibuet, bone-setter and Councillor-General of his canton, was sentenced to pay a fine for having illegally practiced the medical art. His enlightened admirers immediately convened an indignation meeting at a café, and opened a public subscription to cover the amount demanded of their idol by the exactions of a tyrannous law, any surplus to be devoted to the erection of a statue to Sibuet's father, who was also a famous bone-setter. The conveners of this meeting were, in their turn, prosecuted, and mulcted in various sums. This judgment being appealed against, the Chambéry Court has confirmed the finding of the lower tribunal, and

declared that the collecting of money for such a purpose is a contravention of the law.

On the 2d of December, 1890, M. Hallopeau reported to the Académie de Médecine a case of chronic cocaineism induced by a single injection into the gum of 8 centigrams of hydrochlorate of cocaine. From a study of this case, he believes himself authorized to deduce the following conclusions:

A single injection of cocaine, even in a small dose, may not only produce immediate toxic symptoms of a grave character, but may give rise to symptoms persisting for several months. These distant symptoms are analogous to those perceived sometimes immediately after the injection, viz.: obstinate headache, insomnia, numbness of the extremities, attacks of faintness, dizziness, prostration, loquacity and a state of great agitation. These accidents are chiefly observed in very excitable subjects.

In the current number of *La Médecine Moderne*, M. Reclus, who employs cocaine largely, endeavors to controvert these statements of M. Hallopeau, and asserts that, properly managed, this valuable anæsthetic is innocuous. The rules to be followed in the management of this drug are, according to M. Reclus, as follows:

1. The quantity of cocaine injected should never exceed 12 centigrams, 2, 4, 6, or exceptionally 8 centigrams sufficing for most minor operations.

2. Employ a *weak solution* (2 per cent.).

3. Avoid the introduction of the drug into the interior of a blood-vessel. The best way to avoid the evil consequences of such a *contretemps* is to push the needle into the tissue slowly, and while so doing to press on the piston rod at the same rate. In this manner, even if a vessel be pierced, only a small proportion of the solution can mingle with the blood contained in the wounded vessel.

DOMESTIC CORRESPONDENCE.

LETTER FROM NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

Experimental Koch Inoculations—Hypodermic Injections of Aniline and Sterilized Oil in the Treatment of Phthisis—The New York County Medical Association—The New York Medico-Legal Society and Hypnotism—American Electro-Therapeutic Society—Miscellaneous Items.

While it is, of course, far too soon to judge of the ultimate results of the treatment, the very extended series of experiments with the Koch inoculations which have now been carried on in this city have apparently been attended with effects for the most part corresponding with those re-

ported from Germany. There can be no question, however, that the warning note sent out by Virchow has very properly had the result of making our hospital physicians proceed with marked caution in the matter, and it is probably safe to say that in cases of tubercular meningitis, for instance, the lymph will not again be employed. There appears to be sufficient ground for the belief that pulmonary tuberculosis in the early stages of the disease is checked, and may be cured by the injections, and there seems to be a general agreement as to their beneficial effect in cases of lupus.

But even in lupus, according to Dr. P. A. Morrow, the well known dermatologist, while the observations made would seem to show that the results thus far obtained may be regarded as satisfactory and promising, they cannot be called conclusive in any sense as yet. There should be much hesitation, he claims, about declaring that there has been a cure effected in a case of lupus, as it is well known how prone the disease is to break out again after apparent disappearance. A relapse being liable to occur after six, twelve, or even eighteen months, he would not be satisfied that a cure had really been made until the patient had been under observation a very long time.

For some time past Dr. George F. Shrady, editor of the *Medical Record*, has been experimenting with the lymph on cancer cases at the New York Cancer Hospital, and it is even said that it has been used in leprosy in this city, but it does not seem at all likely that any very definite results will be obtained in such cases. William Degan, the consumptive selected by Dr. Shrady from the St. Francis Hospital to be sent to Berlin for treatment, has returned to New York, and is again at the hospital undergoing injections. It is reported that his condition is now considerably improved, but whether this improvement will continue or not is somewhat problematical, as it is thought that the disease was perhaps too far advanced in his case to afford ground of hope for the best results.

In New Haven, Conn., where the Koch treatment was employed for the first time in this country, the injections having been begun on December 3, Prof. Francis Bacon is reported as having said recently: "The original representation in regard to the curative effect of the lymph on lupus are confirmed, so far as the present experiments have gone, but I can hardly say as much regarding its effect on pulmonary tuberculosis. I do not care to express an opinion regarding each individual case, but I will say that there has been an improvement in the condition of the patients, or, in other words, that they are better than they were before the use of the remedy was begun. It is hardly time yet to demonstrate the full efficacy of the lymph, but enough is known to assure us that it is a most powerful agent."

For some time past very encouraging reports have been made concerning the treatment of phthisis at the House of Rest for Consumptives, of this city, by Dr. C. E. Bruce, and at the last meeting of the Medical Society of the County of New York that gentleman reported some of the results obtained by him, and gave an explanation of his method, the essential point of which, it seems, is the hypodermic injection of aniline and sterilized oil in increasing doses. The plan of treatment, he states, is the result of an extended course of investigation into the nature of the tubercle bacillus, and long before the announcement of the discovery of Koch's remedy, he was engaged, assisted by Drs. J. S. Healy and T. W. Rogers, in studying the effects of various substances upon the bacillus. He received his first clue, as it might be called, from a German medical journal, and this leading his thoughts in a special direction finally resulted in the experiments with the remedy named. These experiments have been very satisfactory as far as they have gone, but sufficient time has not elapsed to speak of the results at all definitely. Should these eventually prove as encouraging as Dr. Bruce hopes, he thinks a remedy will be in the hands of the profession which will be free from many of the objections which have been made against Koch's lymph. Thus, it is an entirely harmless material which can be readily furnished to any practitioner in the country, there being no necessity for culture, as in the case of an organic substance like the lymph. Its use can be safely undertaken without the special experiment and careful watching which the employment of the latter demands, and another point in its favor is that as far as the experiments thus far made with it go to show, it seems to be most effective in the advanced stages of phthisis, where the lymph is apparently least beneficial. Since the first of January patients side by side in the House of Rest for Consumptives have been treated respectively by the Koch and Bruce methods, and the results reported have been decidedly in favor of the latter. In this institution, it is to be remembered, that the subjects are, as a rule, in the advanced stages of the disease. The profession has naturally learned to be somewhat skeptical in regard to reported remedies in phthisis, but further developments in this matter will be awaited with interest.

At the annual meeting of the New York County Medical Association the following officers were elected: President, Dr. S. B. W. McLeod; Vice President, Dr. Wm. T. White; Recording Secretary, Dr. P. Brynberg Porter; Recording and Statistical Secretary, Dr. Augustus D. Ruggles; Treasurer, Dr. John H. Hinton; Members of the Executive Committee, Drs. Edward Sanders, N. J. Hepburn, Wm. B. De Garmo, and George T. Harrison. The report of the Statistical Secretary, Dr. Ruggles, showed the Association to be

in a most flourishing condition. One year ago there were 430 members on its roll. During the year it lost by death three members, including the President, Dr. Charles S. Wood, and by removal and other causes fifteen members. On the other hand, it received an accession of 171 new members, so that there are now on its roll 583 active members.

At the last meeting of the Academy of Medicine there was a general discussion on chronic cervical adenitis in children, under the auspices of the Section on Pædiatrics; the discussion on etiology, symptomatology and diagnosis being opened by Dr. A. Jacobi, that on medical treatment by Dr. Wm. H. Thomson, and that on surgical treatment by Dr. Frank Hartley. On this occasion Dr. Alfred L. Loomis was re-elected President and Dr. Edward L. Keyes was elected a Vice-President of the Academy.

At a recent meeting of the New York Medico-Legal Society a special committee on hypnotism, of which Dr. E. Morgan, Jr., was chairman, reported that after a year's consideration of the subject they regarded it safe to say that the following facts had been established:

1. Hypnosis, or artificial trance sleep, is a subjective phenomena, and may be self-induced through expectation alone, through fright, by religious ecstasy, or any enrapturing emotion.

2. Hypnotism is not in itself a disease.

3. Hypnotism is recognized in three stages—lethargy, somnambulism, and catalepsy. The transition may be immediate.

4. Hypnotism has been serviceable in medical and surgical practice, both as a therapeutic agent and in some cases as an efficient and safe anæsthetic.

5. The illusory impressions created by hypnosis may be made to dominate and tyrannize the subsequent actions of the subject.

In the latter part of January there was organized, at the New York Academy of Medicine, the American Electro-Therapeutic Association, composed of physicians in different parts of the country who are specially interested in the various forms of electrical medical and surgical treatment. The following officers were elected: President, Dr. G. Betton Massey, of Philadelphia; Vice-Presidents, Drs. W. J. Morton and A. H. Goelet, of New York; Secretary, Dr. Wm. H. Walling, of Philadelphia; Treasurer, Dr. Geo. H. Rohé, of Baltimore; Executive Committee, Drs. H. R. Bigelow, of Philadelphia, F. H. Martin, of Chicago, Wm. H. Hutchinson, of Providence, R. I., and C. D. Palmer, of Cincinnati.

The report of the Health Department of the city of Brooklyn, recently transmitted to Mayor Chapin, shows that the total number of deaths there during the year 1890 was 19,773, as compared with 18,480 in 1889. The deaths from phthisis amounted to 2,161, and from pneumonia

to 2,319. A much larger number of cases and deaths were reported from diphtheria than any other contagious disease, and not a single case of small-pox was reported. Fifteen thousand births were reported—about 1,000 more than in 1889.

The records of the State Board of Health show that, as usual, November was the healthiest month of the year. It has been found to be the case that invariably the death-rate in the State is lower in this than in any other month. The average daily mortality for the past five years has been 260, while that of November has been 225. In 1889 there were 42 less deaths daily in November than the daily rate for the year; in 1888 there were 52 less, in 1887, 21 less, and in 1886, 9 less per day. The average number of deaths per day in 1890 was 305, and during November 257, or nearly 56 less per day. From zymotic diseases the mortality in November, 1890, reached only 146 in every 1,000 deaths from all causes, and this is lower than the average for the month of November, which is 182 per 1,000.

The 26th of January was a proud and happy day for the Italian colony here. On this occasion there was inaugurated, with appropriate ceremonies, under the auspices of Baron Fava, the Italian Minister at Washington, the "Istituto Italiano," or Italian Home. This institution is located on Second avenue, and occupies a four-story building fronting on the avenue and a two-story building in the rear. Within these quarters are contained a hospital, with wards for both men and women; a benevolent bureau for the relief of the poor, a school for the purpose of preparing Italian children for the public schools, and a bureau for the protection of Italian immigrants and the promotion of Italian colonization. The idea of a benevolent enterprise of this kind has, for a number of years, been in the minds of the leading Italian residents of this city, but it was only when the Chevalier Riva—who is now the Honorary President of the institution—came here as Consul-General of Italy in 1888, that the project assumed definite shape. At his call more than \$20,000 was subscribed; in less than a year by the Italians of the United States. This amount was considerably increased by the dues of those becoming members of the Institute, and the Italian Government, having been made interested in the patriotic scheme, sent a contribution of \$2,000. The promoters of the Home were therefore able, in September last, to purchase the property now occupied for \$31,500.

On the first floor of the Home are the manager's office, dispensary, pharmacy, waiting-rooms and an ambulance entrance. The second floor has rooms for the Secretary and other officers of the institution, a medical board room, a library and a reception room. The latter is a handsome apartment, gratuitously frescoed by a firm of Italian decorators, and contains a beautiful piano, the

gift of Italian piano-makers. All the rest of the furnishing of the room was presented by Signor Salvatore Cantoni, President of the Home, and among the pictures are portraits of Washington, Garibaldi, Mazzini, and the King and Queen of Italy. On the third floor are the hospital accommodations for women—twenty-seven beds in four rooms—and all facilities and conveniences for patients, physicians and nurses, and the fitting-up of this floor has been chiefly paid for by M. Barsatti, editor of the Italian paper *Il Progresso*, in memory of a deceased daughter. The fourth floor is similar in its appointments, and is designed for male patients. The first floor of the rear building contains a large assembly hall for the meetings of the institution, capable of seating 250 people, and it was in this that the inauguration ceremonies were held. On the second floor are rooms for the managing boards of the various departments of the institution, and a large room intended especially for sick Italian sailors. Altogether the arrangements of the new Home are very complete and satisfactory, and reflect much credit on its philanthropic founders. It is estimated that the property is now worth \$50,000, and there can be no question that the institution will accomplish a most excellent work.

In January there died at Flushing, Long Island, a Mrs. Stillwaggon, who was probably the oldest person in the State. She is said to have reached the age of 105 years and 4 months; it being stated that she was born on September 18, 1785. Her birthplace was Tarrytown, on the Hudson, and she came of long-lived ancestors, her grandmother, it is said, having attained the great age of 106. Until she reached the age of 96 Mrs. Stillwaggon did all her own housework and made her own dresses, and on her 102 birthday she made a cake for a church fair.

That inveterate smoking does not always shorten the span of human life would seem to be shown by the case of one Isaac Brandenstein, who recently celebrated his one hundredth birthday in this city. Although very moderate in the use of liquors, he states that he has smoked habitually and freely ever since he was 14 years of age. He can even now smoke most of the day, provided the tobacco used is of good quality, and his only complaint is that good tobacco is too expensive in New York. On getting up in the morning he goes down to the street door and smokes a couple of cigars, after which he eats his breakfast. Then he takes a pipe, and alternates this with cigars, with brief intervals of rest, until 6 o'clock in the evening, when he has supper. He does not take any meal in the middle of the day. He says he feels somewhat "weak and stiff in the joints," but on the whole his health is remarkably good for a centenarian, and on the last Day of Atonement, being a devout member of the Jewish faith, he went to the synagogue early in the morning

and staid there until night, and ate nothing whatever from 6 o'clock in the morning until sunrise on the following day. Still, notwithstanding all this, we would hardly advise anyone who was anxious to attain the age of one hundred years to smoke all day as the best way of attaining this end.

In regard to the agitation existing in various parts of the country on the oleomargarine question, Professor Charles F. Chandler, the eminent chemist, who was for a number of years President of the New York Board of Health, remarks very sensibly: "There is more unceasing and unreasonable opposition to this perfectly healthy and pure product than I know of in any other such direction. Oleomargarine is prepared from beef suet, and it contains precisely the same chemical constituents as butter made from cow's milk; the only difference is that it is produced by a chemical process entirely, instead of partly by the intermediation of the cow. The strong opposition to oleomargarine is instituted for the most part by the farmers who produce butter, aided by the dealers, who find larger profits from the sale of butter than they possibly could obtain from the handling of oleomargarine. The people who pretend to find fault with this beef suet product, however, find no fault whatever with precisely the same material in mince-pies or plum-puddings. Some of the State Legislatures have enacted very extreme laws against oleomargarine in deference to the 'farmer vote,' and the General Government has discriminated against it and against our poorer citizens by placing an internal revenue tax upon it—like the tax upon whisky and tobacco—presumably with the idea that its consumption is detrimental, like the too liberal consumption of tobacco and spirituous liquors. Really, it is 'politics' pure and simple that prevents our people from enjoying, at a nominal price, a perfect substitute and equivalent for butter, the high price of which renders the latter an unwarranted extravagance to many. And all for the votes of the farmers and dealers!"

The reports from the Saturday and Sunday hospital collection thus far received show the very handsome sum of nearly \$55,000, and the returns are still incomplete.

P. B. P.

STRYCHNINE IN SNAKE-BITE.—A controversy is raging in Australia on this subject. The treatment of snake-bite by the hypodermic injection of strychnia was introduced by Dr. Mueller, and evidence of its success has been adduced by other medical men who have tried the plan. Dr. T. L. Bancroft has found, by experiments on guinea pigs, that the method is useless. Recovery from snake-bite, it is well known, does imply cure, and it is not easy in particular cases to distinguish the one from the other.

SPECIAL CORRESPONDENCE.

Report of a Case of Malformation of the Female Generative Organs.

To the Editor:—Without going into the history of the subject or discussing the various classifications of uterine and vaginal malformations, I desire to report the following case:

The patient is 46 years old, married for many years, about 5 feet 10 inches in height, strongly built, and with a decided masculine appearance and voice. Her menstruation has always been regular and easy.

In November, 1890, she had a fall to the ground, alighting in a sitting posture, after which she complained of severe pain in the back and coccygeal region, and from these facts I was led to make an examination. The discovery which I made shed no particular light on the cause of the pain, but it proved to be a matter of interest to me, and explained to the patient the cause of her sterility. In making a digital examination I found the vagina to be roomy, and with two fingers I could reach its upper extremity, but I was wholly unable to find any trace of the cervix uteri. A bimanual examination proved the absence of the uterine body. While conducting this examination a forcible and expulsive contraction of the vagina took place, and at the same time the patient complained of excruciating pain in the back. In a few days I made the second examination, this time with a Brewer's speculum. After the blades were fairly well separated a contraction as above mentioned took place, causing great pain, and with such force that I feared the blades of the speculum would be bent or broken before I could run the button back, allowing the bladder to close.

From the facts recited I arrived at the following conclusion: The vagina and uterus are continuous, and there is no line of demarcation indicating where the vagina and uterus unite. It might be as well to say that there is no uterus, but the vagina is supplied with thick muscular walls, which are capable of wide dilatation and forcible contraction. J. T. McSHANE, M.D.

Carmel, Ind.

The Present Status of the Koch Treatment in Germany.

To the Editor:—I have just received a letter from Berlin, some quotations from which I think will be of special interest to your readers as indicating the present status of the Koch treatment in Germany. He says: "Dr. Koch's remedy is still with us, but becoming less popular daily, if I may judge from students and others who have an opportunity of witnessing the treatment. Beside the French and not a few German opponents who are animated by feelings of rivalry or the like, some there are of late who, closely observing the matter, do not hesitate to condemn the treatment as both fruitless, dangerous and unscientific, since it seems to diminish the patient's strength and physical resistance by its local and general powerful action, and hence a condition favorable to the extension of tuberculosis. Koch's announcement of January 15, besides the disclosure concerning the composition of the substance, gives little more than a repetition of his first declaration for the worth of his discovery. Quite positive indeed is his renewed assertion, but yet, he gives us no additional matter to substantiate his position and encourage the public. A friend of mine, candid and intelligent, who is taking a private course in physical diagnosis under one of Gerhard's assistants, and seeing much of the cases, gives very unfavorable reports. An assistant of Bergmann's also informs me that the number of tubercular patients treated in his hospital has decreased from

some hundreds to a small fraction of one hundred. That of three test cases of laryngeal tuberculosis, with but little involvement of the lungs, under observation for some five or six weeks, and considered favorably at the beginning, two have died and the third is fast after them; that recently one case of lupus was operated upon surgically without any accompanying injection treatment. Bergmann says nothing against the Koch method, but this action is perhaps significant. I myself am inclined to place confidence in Koch and his opinion, with all due allowance for his personal bias, and think we should be very slow to condemn it until we know what he knows." At all events, it is better for the public to be disappointed now, even to an exaggerated extent, before more time and strength is spent in vain.

E. FLETCHER INGALS, M.D.

Chicago, Feb. 10, 1891.

Shall The Journal be Removed to Washington?

To the Editor:—As a member of the Association for thirty-six years, I am in favor of THE JOURNAL being published at Chicago. CHAS. G. BACON, M.D.

Fulton, N. Y., Feb. 10, 1891.

To the Editor:—Keep THE JOURNAL in the central city of the country by all means. No other city presents better advantages for making it a success than Chicago.

HUGH MCCOLL, M.D.

Lapeer, Mich., Feb. 12, 1891.

To the Editor:—The question of the best location for the publication of THE JOURNAL should be discussed with fair argument and common sense.

Does the advertising department greatly assist the financial success of a medical publication? To this question there is but one answer, and wherever published, its advertising pages would not probably be increased beyond their present number, if equalled.

Would the number of subscribers be increased if removed?

From no city could it be distributed more rapidly nor directly than Chicago.

Would the aspiring, disaffected authors of very important original productions all see their names at the head of papers in the first issue after the annual meeting of the A. M. A. if published in Washington, Kalamazoo, or Oshkosh? It seems there has been much nonsense in that line.

Looking at the subject from the standpoint of a country doctor, the editorial work compares favorably with the very best of medical journalism.

Let us keep it in Chicago.

O. A. REA, M.D.

Marmont, Ind., Feb. 12, 1891.

To the Editor:—I have read with much interest the discussion in regard to removing THE JOURNAL to Washington. The scheme—for it is a scheme—is not a new one; I know that certain medical politicians have had it in view since 1886. The chief idea in view has not yet been brought out in the discussion, and perhaps it is just as well to delay the exposure of it until the next meeting, in May. But as yet no one has put forward a single substantial argument in favor of removal.

The most frequently reiterated argument is that as THE JOURNAL is a national journal it should be published at the Capital of the Nation. This is well enough for Fourth-of-July talk, but it lacks a commonsense basis; it is silly, and its silliness has not even the doubtful merit of sentimentality. One may ask, why is none of the money of this country coined at Washington? for the coinage is a National affair. Why not do it all at the Capital of

the Nation? Harrisburg is the capital of Pennsylvania; Why do not Lea Brothers & Co. remove their business and their journals to the State Capital? For the simple reason that they are business men and know that the fact that Harrisburg is the capital of the State will not increase their business. If it were possible to move the Yellowstone Park to Washington there is no doubt that some would be in favor of such a move; and when sifted to the bottom it would be found that personal and private interests were at the bottom. Just so with the scheme to remove THE JOURNAL, as will be made clear when the matter comes up at the meeting in May. I think I know as much of the inside history of THE JOURNAL and of this movement as anyone, and my information is for publication at the proper time.

But the question under consideration is a simple business proposition, and I wish to discuss it from that standpoint. The American Medical Association is in business as a publisher. No publisher can conduct a business successfully except in a business centre. There is no publisher in Washington. Why haven't some gone there "because it is the National Capital?" Because successful publishers are business men. There are several newspapers in Washington, but they cannot be compared with the Boston, New York, Philadelphia and Chicago papers. It would cost more to publish THE JOURNAL in Washington than it costs in Chicago. I make this assertion because I am familiar with printing office details.

For the benefit of the readers of THE JOURNAL that have not access to such information I will show them how many business (trade) journals are published in Washington as compared with Chicago. The following list is taken from Rowell's Newspaper Directory for 1890. Since it was published some other journals have been brought to Chicago from New York and places in the East:

CLASS PUBLICATIONS	IN CHICAGO.	WASH- INGTON.
Religion	51	1
Agriculture, Bee Keeping, Dairying,		
Horticulture, Livestock, Poultry	26	0
Medicine and Surgery	16	0
Deaf, Dumb and Blind	1	1
Children and Young People	7	0
Humorous, Young People	3	1
Law	4	5
Insurance	2	2
Real Estate and Immigration	2	4
Building Loan Associations	2	0
Science, Electricity, Mining, Engineer- ing, Mechanics, Milling	14	1
Numismatics, Philately	1	0
Sporting	10	0
Music and Drama	8	0
Fashions	3	0
Household	3	1
Army and Navy	0	2
Freemasonry	1	0
Knights of Labor	1	0
Oddfellowship	1	0
Other National Societies	3	0
Railway Employes	2	0
Miscellaneous Societies	2	0
Temperance and Prohibition	5	0
Negro	4	3
Commerce and Finance	18	1
Architecture and Building	6	0
Art, Decorating and Furnishing	1	0
Books and Newspapers	3	1
Brewing, Bottling, Liquors and Wine	6	0
Carriages	2	0
Clothing, Furnishing Goods, Tailoring and Ladies' Wear, etc.	3	0
Coal and Gas	1	0
Drugs, Paints and Painting	5	0
Exporting	1	2
Firemen	2	0
Furniture, Carpets, Cabinet Making, etc.	3	0
Groceries, Confectionery, etc.	4	0
Hardware, Crockery, Glassware, etc.	4	0
Hotels	3	1
Jewelry and Watchmaking	5	0
Inventions and Patents	0	2
Leather and Leather Products	4	0
Lumber	3	0

Mercantile Pursuits	1	0
Metals and Machinery	4	0
Photography	1	0

Plumbing and Sanitary
Postal
Paper, Stationery, Printing
Refrigerators
Sewing Machines
Toys, etc.
Trunk and Bag
Tombstones

Further than this, many class journals that have the main office in New York have a branch office in Chicago, and do a large part of the business through the Western office. Many of these class journals are as national as is THE JOURNAL. Why are not more organs of business interest published in Washington? For the same reason that the same kind of publications in St. Louis are not taken to Jefferson City.

It has been said that the business management of THE JOURNAL under Mr. White is not what it should be. But the fact remains that the income of THE JOURNAL from advertisements is now 300 per cent. greater than it was when Mr. White took charge five years ago, when THE JOURNAL was unpopular with advertisers. The income from advertisements should be greater, but it cannot be until certain restrictions now in force are removed. If Mr. White were allowed to conduct the advertising business on the liberal basis of the *Lancet* or the *British Medical Journal*, the income from advertisements could be increased about 50 per cent. or more, in a year, and no one would be injured by it. As the matter stands now THE JOURNAL refuses many advertisements that would be taken by the best and most prosperous journals on earth—the *Lancet* and the *British Medical Journal*. To my own knowledge one of the most vigorous objectors to a more liberal policy in regard to advertisements is a professor in a two-course medical college. Such a man has no right to declaim about the *morale* of the profession until he resigns his Chair or induces his school to reform. No one can conduct a business of any kind on sentiment. No one can conduct a weekly medical journal in this country without advertisements.

It has been said that the list of subscribers to THE JOURNAL has not been increased to the extent that it should have been. The fact is, canvassers have been sent out, but each one has stumbled up against the "no commission for members by application," become disgusted and quit. No commission is paid for such subscribers, and of course no canvasser will work on such terms.

Again, the amount of trouble that has been caused by the fact that the Secretary and the Treasurer of the Association are almost a thousand miles from the office of THE JOURNAL has been and must be very great. Dr. Dunglison and Dr. Atkinson surely know that I say this from no personal motive. But I am stating a fact, and what is necessarily a fact.

But there is another and a most important point. Should THE JOURNAL be removed to Washington, it will cease to be of value as an advertising medium to a very large percentage of its best advertising patrons, and it cannot replace these by others. Any one that knows even a very little about advertising and the business management of a journal can see this, because, with all the journals published in the East, it would be unbusinesslike for firms to make use of a Washington journal, and these firms don't do foolish things.

THE JOURNAL has the field in the West. If it vacate the field it has won to occupy one already more than full, its place here will be taken very soon, for Chicago will have a weekly medical journal. THE JOURNAL cannot afford to drop a substance to grasp at a shadow.

Finally, before it is determined to remove THE JOURNAL, and before the matter is brought up at the meeting, let us know who is to be editor in Washington. THE JOURNAL should have an experienced editor. There are no medical editors in Washington, for none of the medical men there have had editorial experience. Before going down into a well it is a safe plan to have a Strong

man at the windlass. A tyro, however titled, has no place at the head of an exploring expedition.

WILLIAM G. EGGLESTON, M.A., M.D.

Springfield, Ill., February 16, 1891.

To the Editor:—If THE JOURNAL is to be removed from Chicago I am in favor of removing it to Pittsburgh. Next to Chicago Pittsburgh is the greatest railroad centre in the country, and this is a very important consideration in these times of blizzards and railroad obstructions; besides among our more than two hundred physicians, any one of whom is just as capable to edit a medical journal as any one of a like number of physicians in any other locality in the country, either North or South, East or West. But if THE JOURNAL cannot come to Pittsburgh, then I am in favor of it remaining in Chicago, for it was born, cradled and grew to be a man there, and there is where it ought to stay. It is also ably edited there, besides, Chicago is the most central place in the country. Transplanting sometimes does well, oftener not. Therefore, let THE JOURNAL remain in Chicago.

JOHN M. BATTEN, M.D.

Pittsburgh, Pa.

To the Editor:—In regard to the removal of THE JOURNAL to Washington I am of the opinion that it would be a great mistake. THE JOURNAL is not only centrally located, but is ably edited, and a financial success. Under all these circumstances I am of the decided opinion that it should remain just where it is.

SOLOMON MARKS, M.D.

Milwaukee, Wis., Feb. 17, 1891.

To the Editor:—In regard to the removal of THE JOURNAL—Washington is not centrally situated. The Capital has been more centrally located. Let THE JOURNAL remain where it is.

P. C. REMONDINO, M.D.

San Diego, Cal., February 12, 1891.

Official List of Changes in the Stations and Duties of Officers Serving in the Medical Department, U. S. Army, from January 24, 1891, to February 15, 1891.

Major Julius H. Patzoki, Surgeon, granted leave of absence for six months with permission to go beyond sea. By direction of the Secretary of War. Par. 5, S. O. 24, A. G. O., Washington, January 29, 1891.
Capt. William Stephenson, Asst. Surgeon, will proceed without delay from Columbus, Bks., O., to Fort Wayne, Mich., and report in person to the commanding officer of that post for temporary duty, and upon the completion thereof will return to his proper station. By direction of the Secretary of War. Par. 13, S. O. 23, A. G. O., Washington, January 25, 1891.
Major Calvin De Witt, Surgeon, is relieved from duty at Ft. Hancock, Tex., and will report in person to the commanding officer, Ft. Sam Houston, Tex., for duty at that station. By direction of the Secretary of War. Par. 1, S. O. 27, A. G. O., Washington, February 3, 1891.
Capt. Alonzo R. Chapin, Asst. Surgeon (Ft. Yates, N. D.), is granted leave of absence for one month, with permission to apply to the Adjutant General of the Army for an extension of one month. Par. 3, S. O. 17, Dept. of Dakota, St. Paul, Minn., January 31, 1891.
Capt. William B. Davis, Asst. Surgeon U. S. A., leave of absence for seven days granted by O. 2, Ft. Preble, Me., February 4, 1891, is hereby extended twenty-three days, with permission to apply to the Adjutant General of the Army for a further extension of one month. Par. 2, S. O. 22, Hdqrs. Div. Atlantic, Governor's Island, N. Y., February 5, 1891.
Capt. James C. Merrill, Asst. Surgeon, is relieved from duty at Ft. Reno, Oklahoma Ter., and will report in person, at the earliest practicable date, to the Surgeon General U. S. A., in this city, for duty in his office. By direction of the Secretary of War. Par. 5, S. O. 29, A. G. O., Washington, February 5, 1891.
Major William D. Wolverton, Surgeon U. S. A., granted leave of absence for one month, to take effect on or about February 15, 1891. Par. 2, S. O. 15, Dept. Platte, Omaha, Neb., February 7, 1891.
Asst. Surgeon R. W. Johnson, U. S. A., granted leave of absence for one month, to take effect on or about February 10, inst. Par. 1, S. O. 16, Dept. Ariz., Los Angeles, Cal., February 4, 1891.

Official List of Changes in the Medical Corps of the U. S. Navy, for the Week Ending February 14, 1891.

P. A. Surgeon E. W. Anzal, detached from U. S. S. "Boston," and to U. S. S. "Lancaster."
P. A. Surgeon T. C. Craig, detached from "U. S. S. "Vesuvius," and to U. S. S. "Boston."
Asst. Surgeon W. C. Braisted, detached from hospital, Hot Springs, and to U. S. S. "Vesuvius."
P. A. Surgeon H. B. Pitts, ordered to the Army and Navy Hospital, Hot Springs.
Asst. Surgeon W. F. Arnold, ordered to the U. S. S. receiving ship, Vermont.
Asst. Surgeon N. J. Blackwood, detached from the U. S. S. "Vermont," and to "Newark."
P. A. Surgeon Richard Ashbridge, ordered to the Navy Yard, New York.
Asst. Surgeon J. H. North, detached from Navy Yard, New York, and to the U. S. S. "Lancaster."

Official List of Changes of Stations and Duties of Medical Officers of the U. S. Marine-Hospital Service, for the Two Weeks Ending February 7, 1891.

Surgeon H. W. Sawtelle, detailed as member of Board, Revenue Marine Service, January 26, 1891.
Surgeon H. W. Austin, detailed as Chairman of Board for physical examination of officers of Revenue Marine Service, January 28 and February 1, 1891.
P. A. Surgeon W. A. Pettus, detailed as Medical Inspector of Immigrants, Port of Boston, Mass., January 29, 1891.
P. A. Surgeon G. M. Magruder, detailed as Recorder of Boards for physical examination of officers of Revenue Marine Service, January 28 and February 6, 1891.
P. A. Surgeon J. J. Kinyoun, detailed for special duty at Berlin, Germany, January 26, 1891.
Asst. Surgeon J. F. Groenewelt, to proceed to Cape Charles Quarantine for temporary duty. February 7, 1891.

THE KOCH TREATMENT COMBINED
WITH SURGICAL PROCEDURES.¹

From the Surgical Department of the Moabit City Hospital, Berlin.

BY PROFESSOR DR. SONNENBURG,
OF BERLIN

ARTICLE II.—THE SURGICAL PROCEDURES AS
APPLIED TO TUBERCULOSIS OF THE GLANDS,
BONES AND JOINTS.

Surgeons naturally seem to be of different opinions as to the procedures which are indicated in surgery of tuberculous bones, joints and glands, when they have been subjected to the Koch treatment.

I will attempt in the following, with the help of a few specially selected cases, to outline our principles in the treatment of such patients.

First of all, it is absolutely necessary to have a perfect understanding of the action of the remedy, for numerous complications often arise during the course of the treatment which have the greatest influence upon the temperature curve as well as upon the wound conditions.

The fever curve indicates exactly whether or not the action of the Koch remedy is free from contemporaneous influence. When the temperature rises rapidly after the injection and on the following day the fever subsides, we know that these fluctuations of temperature are attributable to the remedy alone.

Patient Kalow, age 18, received in Moabit Hospital July 12, 1890, had resection for disease of the right hip-joint on the 17th of July. The wound was completely cicatrized by the beginning of November; he first reacted in a typical manner on the 25th of November, after injection of 4 mg. Thenceforth he was treated with increasing doses, and each time showed typical reaction. During the treatment the cicatrix showed intense redness, was very painful but did not break open. With the subsidence of the reactions the local disturbances improved; the patient is now entirely well and goes about; he receives from time to time, as

an additional security against relapse, the larger doses of 1 dg.

But there occur deviations from this typical behavior of the temperature curves, and when, more especially, the morning remissions do not again reach the normal, one can be sure that this action of the temperature is conditioned by inter-current complications. These comprise, first of all, the retentions, which are a result of the greatly increased secretion following the action of the remedy.

This can be best observed in operation wounds that have not completely healed or have left fistulas.

These retentions demand immediate free incision and drainage of the cavities, and if necessary, removal even of bones and joint-end, and this is the more necessary because there is, besides the effect of the retentions themselves, a decomposition of the secreted material.

Patient Hasse, age 10, admitted September 11, 1890; *coxitis dextra*; secondary abscess; incision September 13, 1890. There remains a wound surface on the anterior aspect of the thigh which secretes moderately; joint changes are not demonstrable under chloroform narcosis. Patient was subjected to the Koch treatment November 22. After the second injection already there was an irregular rise of the temperature to a great height, with deterioration of the general condition. December 5, the wound was enlarged under chloroform narcosis—as owing to the increased secretion there had occurred some retention of pus—and a sufficiently free drainage for the secretions was established. The temperature now returned to normal; general condition improved, and the appetite, which had been entirely lost, returned. (For result of bacteriological investigations of the wound secretions—*vide* below.)

After the enlargement and drainage of the wound the temperature showed the typical reaction.

The patient now, the beginning of January, receives at intervals injections of 1 dg. The wound on the anterior aspect of the thigh shows but slight suppurative; movements of the hip-joint painless; patient reacts only after large doses.

A quite similar condition appears in the following:

Patient Rueklicke, age 14, admitted in hospital

¹ Authorized translation by Jno. R. McDill, M. D., of Milwaukee, Wis., now in Berlin.

May 8, 1890, for *coxitis dextra*; lungs unaffected. October 24, resection; *caput femoris* completely destroyed; acetabulum perforated. Before the resection wound had quite healed the injections were begun, November 22, but the morning temperature did not fall to normal in the typical manner. The symptoms after the first two doses consisted of slight sense of heat, some redness and sensitiveness to touch about the margins of the wound and a little headache. Without injections the high temperature persisted during the following days; the wound became painful and general condition grew worse. Believing there was again secretion retention in the depths of the wound it was enlarged, and it immediately gave exit to considerable pus. (Bacteriological investigations of this pus showed *staphylococcus pyogenes aureus* in pure culture.) A large drain was introduced and the general condition rapidly improved, pains decreased, appetite returned and temperature gradually subsided and reached normal on the third day after the operation. Injections resumed December 5. The first two doses gave marked reactions and very profuse suppuration from the drained wound; then followed larger doses without marked reactions. On the days when no reaction occurred the temperature remained perfectly normal. The second bacteriological examination showed great quantities of *staphylococcus pyogenes aureus*, besides scattered forms of other bacteria.

This patient is now, at the beginning of January, perfectly cured.

Another case of the temperature being influenced by retentions is the following, which besides shows a number of peculiarities.

The patient Hewart, age 15, was admitted June 9, 1890, on account of *coxitis dextra*.

The patient comes of tuberculous family; says that several years ago he expectorated blood, but never suffered otherwise from anything like lung trouble. The *coxitis* began when two years of age. Resection of joint in 1883; fistulas formed in the cicatrix during the next few years. Re-resection September 30, 1890, on account of destruction of acetabulum; removal of sequestra; drainage. November 22 injections were begun before the wound was healed. Examination of lungs at that time showed a very slight change only in the left infra-clavicular fossa; no râles; no expectoration.

The rises of temperature occurring after injections of small doses, which seemed to call forth general and local reaction, are again owing to retentions. On December 2 the wound was enlarged and again drained; large quantity of pus escaped. (Bacteriological investigation of pus shows *staphylococcus pyogenes albus*.) After this the general condition improved and the fever subsided, but very soon returned and the cause was found in the lungs. On December 7 the

cough and expectoration recurred; tubercle bacilli were present in the sputa in considerable quantity. Some few bacilli had been found in the fluid or liquid expectoration as early as the 24th of November. Râles were found to be increased in the left infra-clavicular fossa. Injections had been made from the 4th to 8th of December, when they were discontinued that the uninfluenced temperature might be observed. Repeated hæmoptysis since December 12. A short time ago we were again enabled to resume the injections and now the dangerous symptoms begin to disappear.

Every retention of pus or secretion matters must have quite the same influence on the temperature, and cause fear, whether the secreted matter accumulates beneath the crusts of lupus or in the caverns of the lungs. This is shown in the case of the 51-year old patient, Neumann, (*lupus faciei et scapulae*).

In this case, after the first injection, unusually copious exudations, partly pus, appeared, the dried superficies of which formed crusts; the accumulation of secretion thereby caused was evidently the reason of slow temperature decline from the 25th to 29th of November, because, after we had removed these crusts, by soaking with compresses saturated with acetate of aluminum solution, typical reactions occurred after the injections; that is to say, there was absence of temperature on the very next day.

Now, it is *not alone the retentions* which cause fever, but also the decompositions (mixed infection) resulting from secondary infection. For in the increased secretion is provided for cocci a favorable soil for growth, and if surgical interference is not soon employed, even septic conditions may arise.

In such circumstances, most likely, is to be sought the explanation for the "pyrogenic feverish after effect" ("*feieberhafte pyrogene Nachwirkung*") of the remedy, mentioned by some authors. When, therefore, for instance, consumptives with lung caverns have a fever persist after injections, it is probably often owing to stagnation and decomposition of the secreted materials within the cavities.

In the case of the patient Hasse (*vide* above), after the exits from the wound had been enlarged, the examination of the wound secretion from the upper fistula, leading to the pelvis, resulted in a pure culture of *staphylococcus pyogenes albus*, from the lower fistula leading around the trochanter—a streptococcus. At this time, January 20, the difference in the natures of these two cocci is clinically illustrated by the fact that the upper (*staphylococcus*) fistula has healed, but the lower (*streptococcus*) still persists. In the case of the patient Hewart, likewise a *staphylococcus pyogenes albus*; in the case of the patient Rueklicke, above mentioned—*staphylococcus pyogenes aureus*.

Quite the same conditions will therefore be observed in other (serous) cavities; whenever retentions occur there is infection-opportunity *through communication from without*. In the presence of such complications the effect of Koch's remedy must be prejudiced, until the removal of the disturbing element is accomplished. In this respect the following case is very instructive:

Pauline Schmidt; tuberculosis of the peritoneum. I had already performed laparotomy on October 16, but the operation was followed by no improvement worth mentioning. At the time, 8 litres of a light-colored serous fluid were removed. On neither omentum nor intestines were tuberculous nodules then visible.

For diagnostic purposes, two guinea pigs were inoculated by injecting into the peritoneal cavity of each 1 ccm. of the ascitic fluid. The animals appeared ill during the first few days, but they soon perfectly recovered. Four weeks after they had the appearance of perfectly sound animals, and four weeks later the autopsies showed no tuberculosis.

The effusion rapidly reformed in the patient. It was removed three times by aspiration. Otherwise her condition remained unaltered. The anæmia and emaciation greatly increased; the abdomen was much distended, the temperature normal, pulse small, lungs showed nothing abnormal, no cough.

On November 24 the first injection of 1 mg. of Koch's lymph was administered, but no reaction followed; on 25th, 2 mg.; great sense of tension in the abdomen, with a marked general reaction. Through the last puncture wound escaped a considerable quantity of a light-brown colored and somewhat turbid serous fluid (compression bandage).

Also during the following days, the fever continuing, the exudation increased to such an extent that punctures had to be repeated several times. Careful examination of the peritoneal fluid shows: A quite clear liquid, which upon standing deposits a very thin layer, resembling pus; in it are found quantities of tolerably well preserved leucocytes and occasional endothelia. Some show greatly enlarged nucleoli, in others there is a yellow, lumpy pigment. Tubercle bacilli not found. Two guinea pigs were inoculated with the exudation fluid. The bacteriological investigation proved the existence of staphylococcus pyogenes aureus (secondary infection).

On December 5 the patient was again laparotomized. Operation was very tedious and bloody, owing to extensive adhesions between omentum and the old cicatrix. The omentum had to be ligated. Tuberculous nodules were visible on the mesentery and portions of the intestinal serosa. Fibrinous deposits. The right tube feels thickened. The wretched and extremely reduced patient died soon after. Result of post-mortem:

Old tuberculosis of the peritoneum, which had recently led to a dense crop of nodules, mainly in the inferior portions. Evidences of recent suppurating peritonitis. In addition there was typical cirrhosis of liver—not tuberculous in origin. Lungs intact. Thickening of right tube was caused by overlying fibrin; mucous membrane and tissue normal.

Bacteriological examination of the fluid, etc., removed at the last operation, results, in one of the three tubes of agar inoculated with the liquid, in four colonies of staphylococcus pyogenes aureus. In contrast to this fluid, which is almost free of bacteria, are the two plates of agar, which were inoculated with the fibrin coagula, showing staphylococcus pyogenes aureus in great quantities and in pure culture.

After reviewing what has been so far discussed, it is our opinion, that in a number of surgical tuberculosis which have open wounds or fistulæ, Koch's remedy, by means of tissue necrosis and increased secretions, together with outward communication of the wound cavities, frequently calls forth changes in the diseased parts which, if surgical interference is not employed, may lead to manifold complications. The action of the remedy can be, thereby, at times completely nullified. Only by the aid of surgical procedure can the typical action and curative effect of the remedy prevail.

Recognizing these circumstances, we have succeeded, up to this time, in effecting perfect cures in some of our surgical cases—*e. g.*, such was the case in the 4-year old patient, Emil Drateva. He suffered from osteitis tuberculosa multiplex. He was under our care since last April, and repeated curettings and incisions had been performed. The injections were begun on November 24.

The reactions in the beginning showed only slight deviations, owing to new abscess formation. On November 26 occurred great swelling and marked sensibility to touch, of the right ankle-joint, which up to that time had been considered as healthy because it had shown no untoward symptoms. In this case we were able to increase the dose rapidly. The reaction ceased completely at 15 mg., and now 5 cg. gives no reaction. The cicatrices on the hands and feet, as well as the right ankle-joint, are entirely painless. The patient goes about and feels very well.

In other patients who had wounds or fistulæ, and in whom large doses caused no reaction, the wounds, fistulæ or glands remained notwithstanding. I should like to remark here, that on tuberculous glands, especially, the effect of the remedy is comparatively slow. The explanation is, probably, that the remedy gains access so gradually

The guinea pigs intraperitoneally inoculated on December 3, appeared to be very ill during the first few days after the injections, but completely recovered (corresponding with the fact that the bacteriological examination of the exudated fluid showed that the fibrin coagula, not the fluid, contained the cocci).

and slowly on account of the encapsulation and the cheesy nature of these deposits. As a matter of course the surgeon has again to interfere in all cases where the self-help of the organism is insufficient to remove the necrotized tissue.

Hence, in all cases in which reaction after large doses repeatedly fails, fistulae, unhealed wounds and joints must be most carefully and completely excised; we have thereby gained very satisfactory results. These patients, however, for assurance' sake, receive large doses of the Koch remedy (1 dg. for each adult, at intervals of from eight to fourteen days). This after-treatment will be continued weeks or months according to the case.

I can, therefore, from recent experience, maintain the principle that, in surgical tuberculosis, the practitioner will have more occasion now than ever before to resort to the knife, and then only will be achieve brilliant results from the Koch treatment. Here least of all is it permissible to limit one's self to the Koch injection according to any prescribed method, for the highest demands of the surgical art must always be kept in view.

A HISTORICAL RECORD OF THE DEVICES USED IN THE MECHANICAL TREATMENT OF SIMPLE FRACTURE OF THE PATELLA.

Read before the Clinical Society of the Chicago Polyclinic, October 11, 1905.

BY CHARLES F. STILLMAN, M.Sc., M.D.,

PROFESSOR OF ORTHOPEDIC SURGERY IN THE CHICAGO POLYCLINIC

In the entire domain of surgery there is not a fracture which has interested more prominent surgical minds, or been the subject of more devices and inventions for its treatment, than this; and in order to present an accurate and comprehensive history, the writer has been obliged to extract freely from foreign authorities, as well as those who have written upon the subject in our own language.

Abulcasis¹ and Paul of Aegina were the first to mention fracture of the patella in their writings. Their treatment was most simple. The former bound down the upper fragment with a bandage; the latter fastened the fragments together with an emplastrum, which with a round splint was held in place by a bandage. Both writers considered the extended position of the limb a necessity. It is unfortunate that no illustrations can be obtained depicting their methods.

Guido, Theodorich,² Giul. de Saliceto and Brunschwig recommended plasters, splints and bandages, and even Paré considered the subject briefly and with no positive directions for treatment. He suggested that compresses be laid in the popliteal space, and splints of straw used to prevent flexion. Paré asserted that he had never effected a cure without deformity, a limp always remaining in

the patient's walk. This assertion seems to have acted as a spur to surgical invention, and was followed by many devices to overcome the difficulties to which he referred. Peccetti (1557) attempted to fasten the fragments together with a leather ring which was held in place by a bandage. More complete was the invention of Muschenbroek, a mechanic of Leyden.

This is described by Solingen³ and mentioned by Garengot,⁴ who drew attention to the favorable comment it had occasioned in France, although it had been claimed by Arnaud, though he neither invented it nor brought it personally from Germany. Muschenbroek's apparatus consisted of two steel plates padded, and these were screwed on to a frame of the same material, and by means of straps the fragments were kept in approximation (See Fig. 1).

The next important form of apparatus was devised by Purmann,⁵ and consisted (See Fig. 2) of an iron ring, covered with leather and secured in place by straps.

The first complete monograph upon the subject of fracture of the patella was written by Dr. H. Meibom⁶ (1697), and in this dissertation he described the method and splint invented and advocated by his father.

This consisted of a padded cap that encircled the fragments, and could in its upper part be opened and closed at will. The eighteenth century was very rich in contrivances to effect union.

Petit used a form of gutter padded with Hungarian leather (Fig. 3), which was provided with side slots in which the bandages were fastened. He used two bandages, in the middle of each of which were sewed semicircular padded compresses which crossed above and below the fragments, and Verduc⁷ (1711), Henckel (Fig. 4), Bass⁸ (Fig. 5), Eschenbach⁹ and others, used compresses and many-tailed bandages in various forms. Kalschmidt¹⁰ used a linen crown covered with a wooden capsule with a square opening at the top (Fig. 6).

Valentin¹¹ (1772) was the first to draw attention to the value of placing the limb in a satisfactory position by relaxing the extensors, and elevating the foot so as to approximate the fragments.

Theden¹² soon after drew attention to the inefficiency of the ring and other forms of compressing apparatus, and strongly advocated the position treatment of Valentin. Theden was the first to place the limb in a box, the lower end of which was elevated to maintain the extension, and the fragments were held together by circular loops and bandages.

Bell¹³ (Fig. 7) used two heart-shaped compresses finished in leather, connected together by two girths, one of which passed around the limb above the knee and the other below. These compresses were drawn together by other straps, the fragments of the patella being between them, and

the upper compress was connected with the end of the shoe by a long anterior strap which was intended to prevent flexion and displacement of the upper fragment. The leg was directed to be retained in position in this apparatus fourteen days.

Zenker changed the form of these heart-shaped compresses into that of the horse-shoe, and Bucking¹⁴ (Fig. 8) and Evers followed with slight modifications.

The next important improvement after Valentin's in the treatment of this fracture was that of Souville.¹⁵ He bound the thigh with bandages from the hip downward, and from the foot upward to the knee, to control the action of the extensors and overcome the swelling of the knee-joint. He reports one case treated by this method in which the patient began to walk in twenty-nine days. Richter¹⁶ also used this bandage, and asserted that he never felt the need of any other instrument or dressing. Böttcher¹⁷ placed a compress and spoon-shaped splint posteriorly, and fastened it so that the fragments were held by the girth straps above and below the knee, connected by linear straps which kept them in position. Lampe¹⁸ (Fig. 9) modified the apparatus of Bucking (Fig. 8), which was substantially that of Bell (except that the heart-shaped plates were united by hinge rods instead of straps), by substituting screws for the hinge rods, and these screws were provided with pivots where they were attached to the plates, so that the latter could better adapt themselves to the curves of the limb.

The beginning of the nineteenth century was also rich in inventions. Desault and Richerand¹⁹ were the first to advance plans of treatment, but the essential principles of their methods were incorporated in the apparatus of Boyer²⁰ (Fig. 10).

This consisted of a thin metal gutter thoroughly padded, and sufficiently long to receive the entire lower extremity. To this were fastened by buttons two well padded straps of leather passing above and below the patella.

Boyer's gutter greatly resembled Buirer's (Fig. 11), and the suspicion could be entertained that the latter had served as a model for Boyer's, since it was in use prior to 1801.

Buirer's²¹ apparatus consisted of a long gutter or splint, carved to fit the posterior surface of the limb, and in which, as in Boyer's, were two straps fastened by means of buckles, holding between them the fragments of the patella.

Assalini²² contrived a dressing (Fig. 12) in which, in addition to the rest of the apparatus, the thigh was placed in a cylindrical splint, and four crossed straps were used instead of two to retain the fragments in position.

Sauter recommended his suspension frame for this fracture, and fastened the outstretched limb on the same, but neglected to give his suspension the form of an inclined plane.

Sir Astley Cooper used a hollowed splint, allowed the patient to sit upright, the heel being elevated, and waited until all inflammation had subsided. He then bandaged the limb from the foot to the knee, pressed the upper fragment downward, laid on each side of the knee a broad band and fastened the same with circular loops above and below the patella. The ends of the strips, which had been laid along the knee, were then turned over and tied together, thus tending to approximate the circular loops, and with them the fragments (Fig. 13).

Another device for which he claims still more excellence, is the employment of a leather band around the thigh above the upper fragment. This is connected to the sole of the foot by straps passing down each side of the leg, which is maintained in an elevated and outstretched position (see Fig. 14). This was contrived with the evident object of overcoming the contractility of the muscles of the thigh.

To prevent these long side straps from slipping, circular bands about the leg are to be used as shown in Fig. 14.

He recommended the retention of this position for five or six weeks, and after this passive motion.

Sir Chr. Bell²⁴ used a simple bandage. He bound down the upper fragment first by passing the bandage under the knee in the popliteal space. The lower fragment was treated in the same manner, and he paid especial attention to the directions of his predecessors as to position.

Langenbeck, and also Richter,²⁵ bound up the leg and thigh, the fragments being held together only by a few circular turns of the ends of the bandage. They did not use an inclined plane, but instead had the patient sit in an upright position. Dupuytren²⁶ used a very simple bandage to maintain the fragments in position, and placed the limb on an inclined plane.

Von Graefe²⁷ (1824) was the first to devise a splint for this fracture, provided with joints at the side. (Fig. 15). It consisted of two semi-circular troughs made of sheet iron and properly padded, united by two lateral hinge joints. The splint is fastened to the limb by means of four girths, two of which are placed on the upper half and two on the lower half of the splint. Union of the fragments is sought to be accomplished by means of two linear straps connecting the middle transverse ones.

Amesbury's²⁸ apparatus consisted of two leather cushions, the larger being placed over the upper fragment of the patella, and the smaller one the lower, so that after being buckled together they hold the fragments between them. From the upper cushion a strap passes down along the leg to the sole of the foot, under the same and back again up the other side of the leg to the opposite side of the same cushion, to which it is then

buckled, (Fig. 16). Before the application of the cushions, the limb is laid upon a long carved wooden splint, extending from the os ischii beyond the heel, to which it is fastened partly by the straps attached to the cushions and partly by other bandages and straps. (Fig. 17).

A similar dressing was next invented by J. L. Rosseau, of Philadelphia, (1826). (Fig. 18).

After the outstretched limb had been placed at an obtuse angle with the body, and the fragments had been approximated, a small stuffed pillow was placed against the upper fragment and fastened there by straps and girths. At a distance of two inches above and below the patella were placed two girths, the upper one of which was connected to the foot by a side strap as in Sir Astley Cooper's and Amesbury's contrivances, already described. A splint eighteen inches long was next placed under the limb, its centre being under the popliteal space, and on each side of this splint there were narrow slots for the side straps to pass through. This splint was secured to the limb by roller bandage and the patella was covered with a compress which was held in place by another girth encircling the limb and the splint.

F. W. Fest^o (1827) arranged an inclined plane for which were claimed special advantages. (Fig. 19). It consisted of a wooden adjustable inclined surface, furnished with folding sides, and at its lower end with a sliding board to increase or decrease its length.

Two longitudinal slots were cut in the board opposite and under the knee for the passage of the transverse crossed straps which were intended to keep the fragments in apposition.

To and under the end of each strap furnished with buckling holes, are fastened padded girths, one of which is laid against the upper, the other against the lower end of the patella in a horizontal direction, which serve to hold the fragments in position when the straps are buckled. To more firmly secure both girths in the desired position, two small straps are fastened at right angles to the upper edge of the lower girth and secured to the upper girth, and thus, in a measure, prevent deviation of the fragments to one side. To prevent the apparatus from falling over, two large and two small wings are secured to the side of the lower end, and in the middle of the foot-rest, these being joined by hinges to allow their folding together. Richter (1828) observes that what Valentine and Theden had sought to attain through comfortable position had previously been attempted by surgeons with machines, without satisfactory results, they not being able to prevent the contraction of the extensors. From an historic study of the subject he notes how one sees even in his time a return to simpler methods of treatment, and he states that when the importance of this treatment is fully realized, and the fact that all new forms of contrivances

are constructed mainly on the same principles, the means to bring about a perfect union are recognized to be nearly analogous to those of the more ancient days. The indications which must be fulfilled, observes Richter, in the treatment of fracture of the patella, are 1, the prevention of the contraction of the extensors, 2, the maintaining in contact of the fractured surfaces, and 3, the prevention of the swelling of the limb. In accordance with the first indication, he advises that the patient sit upright, the outstretched limb to be placed on an inclined plane, and the thigh bandaged from the hip-joint downward. To prevent the foot from falling from one side to the other he suggests that the limb be placed in a steel semi-circular padded canal or placed between straw splints and compresses used. The second indication he considers can be accomplished by winding bow-formed circular turns of bandage above and below the patella, these being connected together in the popliteal space; or again by the use of the "Testudo Inversa," of which Kluge made especial mention. To obtain this a sufficiently long pasteboard splint is laid posteriorly and it is padded with linen, particularly on the edges, to prevent pressure, and leaves a hollow in the middle so that the circulation in the vessels of the popliteal region cannot be disturbed. This splint is fastened by a few circular turns above and below the knee.

Alcock^o was the first to advocate the use of the adhesive plaster of modern times in this fracture, although Paul of Aegina, centuries ago recommended holding the fragments together with an emplastrum, and was evidently actuated by the same desire to employ adhesive material in their retention.

A hæmorrhagic condition of the joint need not prevent the application of this dressing, but Alcock directs that the knee must remain free if the swelling is inflammatory. The treatment lasts several weeks, and its duration is governed by the individuality of the patient. He considers that four weeks might suffice with a young person, but with older patients and under unfavorable circumstances, a longer time must be deemed advisable.

The given time having elapsed, he states that passive movements can be allowed, the patient still remaining in bed, and not until the patient has acquired skill in moving the knee must crutches be used to practice walking. He must exercise gradually until he depends on a stick, and only in the end do away with that. Richter draws attention to a useful contrivance to prevent the tearing of the newly formed ligamentous tissue, invented by Baillif.^o (Fig. 16). It consists of four portions of steel with leather, and padded on the inside, of which two are buckled to the thigh and two to the leg. By a point which only allows twenty-four degrees of flexion,

excessive motion of the leg is prevented, this often being a causation of ligamentous rupture. To prevent these splints from slipping downward, the outer segment is joined by means of a strap to a girth which surrounds the pelvis.

At present the greater number of forms of apparatus for pressure upon the fragments of the patella are derived from Muschenbroek's, (Fig. 1), already described, or from the apparatus of Boyer (Fig. 10), which consisted of a straight gutter with double straps, and represents the most simple model and the best known and the most often reproduced. The great number of forms belonging to these two classes were fifty years ago almost entirely abandoned because of insufficient action and inconvenience, as was well shown by Malgaigne in his dissertation upon the subject, but during the past half century great activity in invention has been displayed. In Langier's² apparatus, Boyer's gutter was replaced by a horizontal plank covered with a thick cushion and large enough to enable the supporting strap to be maintained at a distance from the lateral parts of the limb. This plank is furnished opposite the popliteal space with two pieces of wood, serving to regulate the straps. Instead of the padded straps before that time in use to brace the fragments of the patella together, Langier applied to each fragment a small piece of gutta percha carefully cast. Each one of these is solidified on the fragments and a circular band of caoutchouc is utilized also. This is a simple apparatus, leaves the parts uncovered, is easily applied and looked after, is not liable to accident, and is possessed of sufficient qualities to give good results. Wood's³ apparatus is quite similar, and consists of metallic blades placed behind the limb, furnished with two hooks turned in the inverse direction which serve as points of attachment to bands of India rubber, crossing themselves on each fragment.

Lonsdale's⁴ apparatus is composed of two covered metallic plates, semi circular in form and slightly concave beneath, thereby adapting themselves nearly to the form of the patella. These two plates are attached to iron supports which slide laterally on transverse bars arranged in such a manner as to move from top to bottom on two vertical rods, placed on each side of the knee and riveted to the posterior blade. The supports and horizontal rods are furnished with screws which allow the parts to be adjusted in any desired position, horizontal and vertical adjustment being both permitted by the arrangement.

Fontan's⁵ apparatus is of two forms—one is composed of a board of more length than width from the angles of which rise rods, retained at their position by iron triangles. These support two rods, each one receiving a strong wooden screw. These are hollowed two or three thumbs length, and this canal receives the free extremity

of a strong iron wire surmounting the two half circles. The last named are important pieces of the apparatus, and press on the superior and inferior parts of the patella. These operate reversely, and their pressure is augmented or diminished as desired by tightening or loosening the wooden screws. To prevent their sliding on the fragments, a slight curvature is imparted to the stem of the wire which supports them, and to still further insure a good result, to the extremity of each piece is added a strap which is received in buckles placed on the sides of the board that constitutes the foundation of the apparatus. The half circles are movable. The foundation is covered with a linen cushion thick enough to raise the knee and lessen the strain upon the popliteal region. The limb is introduced between the poles, the fracture resting in the centre of the apparatus. After the rods and triangles are properly adjusted, the iron wire stem of the half circle is inserted in the central canal of the screw, and after securing the half circles by aid of straps, the union of the fragments is effected by tightening the screws. The second apparatus invented by Fontan is better known and more simple; its action, however, is less efficacious. It is a modification of Boyer's apparatus. In this second contrivance two circular bandages are placed above and below the patella. These are introduced in the half circles with which the foundation is furnished, and approximate the transverse bandages to the limb by means of lateral girths. In spite of all the care given in applying these forms of apparatus, they produced only fibrous union, and Bonnet recommended that whatever apparatus was used the heel should not be elevated above twenty to twenty-six inches, thus to avoid producing a harmful tension in the muscles of the posterior region of the limb.

Malgaigne's⁶ hook apparatus was invented to effect the union of the fragments to the necessary degree, to result in the formation of osseous union. Its employment was advocated when the separation exceeded two inches, because then a fibrous union was almost inevitable if the ordinary bandage was used. This instrument has its support on the bone itself without the assistance of bandages or splints. It consists of three inch large steel plates so arranged as to slide one upon the other, and separated or brought together by means of a horizontal screw parallel with the plates. This screw engages itself in a hollow in the centre of the two riveted bolts on each of the plates and is turned by means of a key. The free extremity of each plate is bifurcated, ending in two very pointed curved hooks resembling those of a double forceps. The two hooks of the inferior plate are separated by one inch only, and are implanted on the summit of the patella in such a way as to lodge their points in the bone. Those of the superior plate are separated twice

Fig. 32.

as much. The inside hook is longer, to accommodate itself to the obliquity of that part of the bone. To avoid the evil effects which were sometimes shown to be produced by Malgaigne's hooks, Rigaud, of Strasburg, proposed to replace the hooks with two metallic stems, which are to be introduced not only in the fibrous tissue, but in the patella itself. He used two screws which he implanted in the fragments and afterwards brought together by the aid of girths and a metallic arch.

Bonnet²⁷ (1851), of Lyons, adopted the use of the screws implanted in the patella with the precaution not to let them penetrate further than 4 to 5 millimeters. Two screws surmounted each fragment with a quadrangular frame of 3 millimeters in height, and were implanted in the intermediary parts of the fragments to within one millimeter of the fractured borders. Meanwhile, as an assistant approximates the fragments as much as possible, the surgeon fixes them in a

state of coaptation by encircling them with bandages. He next presses them together with two little steel branches united by two screws. The application of this procedure, more theoretical than practical, was not effected without difficulty, and inconvenience.

A. Cooper's²⁸ procedure (of San Francisco) went very much further, and he proposed to unite the fragments by metallic sutures. A longitudinal incision sufficiently long to uncover the fragments having been made over the patella, these were pierced obliquely with a drill and the surgeon passed through these perforations silver sutures whose extremities were to be twisted until the fractured surfaces were brought into immediate contact.

In all the recent interesting papers upon the feasibility of wiring the patella, the writer has failed to find credit given to this American surgeon who was evidently its originator.

Trélat's (1862) apparatus consists of a very in-

genious combination of gutta-percha and the hooks. He uses the efficacious action of the last in bringing the fragments together, and evades by the interposition of the gutta-percha the wounding and inconvenience resulting from the implantation of the hooks. Before using this apparatus it is necessary to wait until the inflammatory swelling has disappeared, and the surgeon then applies it in the following manner: Two plates of gutta-percha are cut and softened by plunging them into hot water, and while the member is maintained in the forced extension at an angle of forty-five degrees, the surgeon places them on each fragment in such a manner that their greatest extremities face each other. With wet fingers the surgeon models the gutta-percha to the contours of the patella and the neighboring points. It is necessary that this modeling should be done with a great deal of care, as the efficaciousness of the entire apparatus depends on its exactitude. Bandages dipped in cold water are then applied on the gutta-percha, and as soon as the plates are hardened enough to be taken off without alteration, the surgeon plunges them into a vessel filled with cold water, where in a few moments they recover their normal consistency. The surgeon then adapts them anew to the parts, which they fit without the interposition of any foreign body. He then fixes them to the surface at their pointed extremities with the aid of a small starched bandage wound once or twice around the limb. Without this precaution the moment the hook was applied each plate would tilt and the hooks would immediately cease to operate. The surgeon then brings by aid of the fingers each plate toward the other and implants strongly in each the corresponding half of the hook. And he need have no fear of piercing the gutta-percha and arriving as deep as the skin, for the gummy substance can only be penetrated with difficulty and the point rarely attain half its thickness. There remains nothing more but to screw together the plates and fragments to the degree desired. The surgeon next places the limb in a gutter of which the inferior extremity is elevated to thirty-five or forty degrees. At the end of several days the soft parts yield, and he must then take the plates off the limb and re-adjust the entire apparatus. After a month this splint has afforded all the results that can be expected and the hooks are to be taken off. But Trélat advises leaving the limb during several days afterwards in the extension position. He claims that this apparatus causes no suffering, procures a uniform pressure over a large surface, is not liable to accident, and allows the examination of the state of the fracture through the spaces between the plates.

Valette's apparatus (of Lyons), is composed of an iron gutter well padded, supplied with four straps and disposed in such a manner as to re-

ceive the entire limb. The one here presented is furnished with a sole to support the foot, but a gutter which would embrace but a part of the leg and thigh could be employed. Opposite the articulation two blades of iron arise connected by an arch which is perforated in its centre for the passage of forks. This arch can be raised or lowered by being placed in the slots in the up-rights—the forks being regulated by a key. This apparatus is claimed to advantageously remedy the defects which Malgaigne's hooks present.

Prof. Gross,¹⁰ of Philadelphia, recommended the employment of a padded tin case extending from the middle of the thigh to a corresponding point in the calf of the leg. A roller is to be applied upon the leg from the toes upward, and another upon the thigh from the groin downwards, the displaced fragments to be brought down and confined by numerous adhesive straps carried around the bone above and below the joint, and connected afterwards by vertical and transverse pieces. A long, thick and very narrow compress should extend around the upper border of the patella and confined by the two rollers, passed around the joint in the form of the figure 8.

Dr. Sanborn,¹¹ of Lowell, Mass., suggested a method by the use of a single adhesive strip twisted above the knee. He directs that a strip of ordinary adhesive plaster four feet long, and two and a half inches wide, be applied to the limb from the upper portion of the thigh to the middle of the leg, leaving at the knee a free loop. (Fig. 29.) A roller bandage is then applied above and below the knee for the purpose of securing the plaster and controlling the circulation and muscular contraction. A small stick six or eight inches in length then being put through the loop over the knee, the plaster is to be twisted until the patella is brought near down to its proper situation. Before applying the twist, a hard compress is to be placed above the patella in such a manner as to bring the force to bear directly upon the bone.

Prof. Frank A. Hamilton contrived a dressing consisting of an inclined plane of sufficient length to support the thigh and leg, and about six inches wider than the limb at the knee. (Fig. 31.) This plane rises from a horizontal floor of the same length.

Wales¹² draws particular attention to the merits of the forms of apparatus devised by two American surgeons, Lansdale and Hartshorne. Of the former (Fig. 32) he terms a very ingenious and efficient splint—holding the fragments in exact apposition and not constricting the limb. "It is constructed with a posterior padded splint upon which the limb is secured with a roller bandage." "From a point a short distance above the knee an iron loop, or arc, spans the limb obliquely, and when in position its top is below the patella; a simi-

lar arc is fastened to the splint at a corresponding point below the knee, and its top, when in position, is above the knee. Each of these arcs bear a screw at its centre armed with a semi-lunar pad. In the application of this apparatus after the limb is secured to the splint, it is simply necessary to bring the upper fragment down, and with the upper screw clamp the pad against it; in like manner clamp the inferior fragment with the lower pad.

Dr. Edward Hartshorne first employed his method in the Pennsylvania Hospital in 1862, and it consists of a simple application of the Spanish windlass.

The splint, which should be carefully padded—and sufficiently broad—is furnished on its sides, at proper distances above and below the knee, with notches or projecting cleats, pins or hooks which are required to hold the bandage. This bandage may be the common roller or adhesive strips, or even a band or ring of elastic webbing; but inelastic webbing, or linen, or cotton drilling from one and a half to two inches wide in the central portion and narrower at its ends, answers better, especially if the surfaces which we apply to the integument above and below the fragments are thinly spread with old adhesive plaster. The lower fragment is fixed in the usual way, and retained in position by simply applying one of the bandages by its wider central portion in front of the knee-joint directly to the lower margin of this fragment, then passing the two narrower ends obliquely upwards and backwards and drawing them firmly together over the upper cleats, pins or notches, and behind the splints, there to be fastened in any manner most convenient.

The bandage or band for the upper fragment requires more careful application and adjustment, as it is to exert all the pressure and traction force necessary to bring the fragment down, and retain it in apposition with the fixed lower fragment. Having been applied to the integument just above and slightly over the margin of this upper fragment, it is then drawn firmly downwards and forwards over the notches or cleats in such an oblique direction as may be found the best for efficient traction in each particular case. The two ends are firmly fastened together, and a small stick (or, what is better, the little wooden fork called a clothes-pin), passed between the band and the splint, is turned or twisted on its long axis in such a way as to draw upon the bandage to any proper extent. This arrangement allows the whole knee, especially the injured parts and the compressing bandages, to remain uncovered, at the same time that it gives entire control of the joint and of the separated fragments, as well as of the dressing itself. Compresses of lint or other material may be employed, but they are not often needed, particularly when adhesive plaster is spread upon the central portion of the bandage. Tilting of the fragments may be prevented by a transverse bandage, or by a narrow, well-padded transverse splint pressing upon the line of fracture. The ease and certainty with which the traction may be lessened or increased by the slightest turn of the twisting-stick or pin, at the same time that this pin may be fastened beyond the reach or control of the patient, renders this contrivance remarkably effective; while the simplicity of materials and arrangement bring it readily within the reach of every one. The same care in all essentials, and especially in adapting the splint and bandage, as to length and width of the former, and the distance apart of the cleats or notches, and the width and obliquity of the latter, must be observed in the use of this mode of dressing, as in other more complex or different arrangements.

From Erichsen¹⁰ whose remarks upon the treat-

ment of this fracture twenty years ago, may be taken as an index of the professional opinion existing at that time, is extracted the following.

There is rather severe inflammatory action in the knee with great synovial effusion. This requires to be reduced by rest, and the application of evaporating lotions, before any other treatment can be adopted. When this has been effected, means must be taken for the reunion of the fragments. With this view the principal point to be attended to is to keep them in sufficiently close apposition for firm ligamentous union to take place. With this view the upper fragment, which is movable, and has been retracted by the extension muscles of the thigh, must be drawn down so as to be approximated to the lower one which is fixed by the ligamentous patella. This approximation of the fragments may be effected either by position and relaxation of the muscles or by mechanical contrivance. Simple position usually suffices for this purpose, and must be attended to whatever mechanical appliances are used. By placing the patient in a semi-recumbent position, and elevating the leg considerably so as to relax the muscles of the thigh completely, the upper fragment may be brought down to the lower one, and if necessary may be retained there after any local inflammation that results from the accident has been subdued—by moulding a gutta percha cap accurately to and fixing it firmly upon the knee, or by the application of pads of lint and broad straps of plaster. These straps of plaster may be applied above and upon the upper fragment in a diagonal direction from above downwards. They should be of sufficient length to embrace the limb and the back splint, to which they are to be fixed, or a figure of 8 may be applied around the limb and splint together. This position must be maintained for at least six weeks: At the expiration of this time the patient may be allowed to walk about, wearing, however, an elastic knee cap, or what is better, a straight leather splint in the ham, so as to prevent the knee from being bent for at least three months.

In conclusion: this paper has been prepared solely with the idea of presenting to the profession a concise résumé of the more important forms of apparatus which have been invented for this fracture prior to the last twenty years, and as its details are familiar to every practitioner, no mention is made of the present practice of encasing the limb in plaster-of-Paris, although this must also be considered a mechanical procedure.

The writer in this paper, which is intended to be entirely historical, does not enter into the controversy at present existing between advocates of operative and mechanical treatment, although

this subject is now attracting widespread attention in the profession. It is, however, safe to assume, that so long as a surgical operation to secure union of the fragments is not unattended with danger, excepting under antiseptic precautions, the details of which render its employment impossible for ninety-five practitioners out of a hundred, especially those residing in the country, the mechanical treatment being devoid of danger, and productive of a fairly good result with but little comparative inconvenience, will interest and continue to be employed by far the greater majority of the profession.

125 State St., Chicago.

METHYL-VIOLET.

Read at the Missouri Valley Medical Association at Kansas City, Mo., December 26, 1900.

BY FLAVEL B. TIFFANY, M.D.,

OF KANSAS CITY, MO.

A few months ago Dr. J. Stilling, of Strasbourg gave to the world in the *Revue Generale d'Ophthalmologie* his experience in the use of methyl-violet in the treatment of various affections, more especially those of the eye. When the article first appeared, May, 1890, I took the liberty of translating it, and subsequently my translation was published in two numbers, (non-consecutive) of Dr. Lamphar's *Kansas City Medical Journal*. I commenced the use of methyl-violet from the day I first read Prof. Stilling's article, for at that time I had on hand a case of suppurative iritis which had resisted all treatment, continuing step by step through the several stages of inflammation until panophthalmitis seemed inevitable.

The patient was an old man, 72 years of age, rather feeble physique, upon whom I had made extraction of a nuclear cataract some eight weeks previous to the attack of iritis. He had made a good recovery from the operation and with fair results, viz., with plus 11 D. $\frac{3}{8}$. Could read No. 2 with + 14 D. There was a slight amount of cortical substance remaining. The iritis did not ensue for a month after he had gone from the hospital, when it appeared quite suddenly one day as he was sitting in the harvest field watching the harvesters at work. He says that as he crossed the lot from one shade tree to another, in the full blaze of the bright August sun, he felt a sharp pain dart through the eyes, and from that time he was not fully free from pain, which gradually increased with intolerance of light and diminution of vision. It was several days after the attack before the patient returned to the city. When he presented himself I found an intense inflammation of the iris with plastic exudation in the front chambers.

Mydriatics and hot water were scrupulously used in connection with other antiphlogistics, but all to no purpose, the inflammation mounted higher and higher, and the exudation was more profuse and of a suppurative character; the iris becoming a deeper red until finally the whole chamber became blood red; the cornea began to grow steamy, there was intense ciliary injection; in fact the whole ball was aglow, and the lids swollen. There was much pain and total blindness. I despaired of any chance of saving the ball, much less any sight.

It was at this stage that I read Dr. Stilling's article on methyl-violet. I immediately had a preparation made, 1 to 1,000, which I had dropped into the eye, one or two drops at a time, thrice a day. This caused no irritation, but for a few hours there was little, if any, amelioration of the inflammation, although the eye felt better. At the end of the second day there was perceptible abatement of congestion, and the pain was nearly gone. The amount of medicine was increased. The conjunctival sac was filled at each application, morning, noon and night, and the inflammation gradually subsided.

The methyl-violet was continued for about three weeks, when the eyeball had become clear and free from inflammation. The shape and size of the ball had been perfectly conserved, the iris had assumed its natural color and brilliancy, although the pupil was nearly occluded and there was only perception of sight. The patient returned to his home in Kansas with the hope, through the means of a subsequent operation (to be made in few months) of regaining useful vision.

It has been about six or seven months since I commenced the use of methyl-violet in affection of the eye. I have used it a great many times, and in many patients, and have kept a careful

record of several of the cases. It has been mostly used in phlyctenular conjunctivitis and granular conjunctivitis.

In cases of trachoma, when treatment cannot be continued by me on account of patients being obliged to return to their homes, out of the city, it has become my custom to prescribe a bottle of methyl-violet (1 to 1,000) to be used at home three times daily, and it has been invariably the case that these patients go on to recovery without any relapses, and that the medicine never acts as an irritant, but is always soothing and agreeable. I have used it with excellent effect in dacryocystitis by means of the lachrymal syringe. I have also used it in otitis media purulenta but not with as marked benefit as in affections of the eye, lachrymal apparatus, and nasal catarrh.

I have employed this agent in microscopy as a staining material, knowing its special and thorough action as a stain for different forms of microbes, and especially for the micrococci, and that it always means death to the bacillus when it comes in contact with him; striking, as it were, to the heart or nucleus of all cells; paralyzing all vital action at once; but it had not occurred to me to employ it as a therapeutic agent even in those diseases which are generally conceded to have their etiology in the microbes, until my attention was called to it by Prof. Stilling's able article to which I have referred.

Since I have been using this agent I have not had the opportunity of employing it in a single case of gonorrhoeal ophthalmia. As yet, of course, the remedy has not been sufficiently used to establish it as so valuable a remedy as Dr. Stilling would claim for it.

Methyl-violet may be used as a local, topical and general systemic agent, in fluid or pomade, spray $\frac{1}{10}$ to 1 per cent. It remains to be seen if it shall prove a valuable remedy in pulmonary affection, in pyæmia, etc. If it has a special predilection for the bacillus and cocci, we shall look for it as a boon in most diseases.

Within the last few days I have had occasion to use the methyl-violet in two cases, one of iridocyclitis and the other choroido-cyclo-iritis, both of a most serious nature; that of iridocyclitis occurred in a reverend gentleman, Mr. D., age 55, blue eyes. This patient consulted me December 9, complaining of quite a severe pain in the right eye, with dimness of vision. Examination revealed acute inflammation of the iris with intense deep red congestion of the sub-conjunctival vessels over the entire anterior scleral surface. The pupil was contracted and inactive, and would not respond in the least to mydriatics. A 1 per cent. solution of sulphate of atropia dropped into the eye five or six times a day made no impression whatever, not even controlling in the least photophobia or congestion; in fact all the symptoms grew steadily worse, and on the third day the cornea lost its

transparency, became steamy, so that the iris was nearly hidden and the vision was gone; could not see to count fingers, and the fellow-eye had taken on symptoms of irritation, and its vision was considerably reduced. At this period, December 11, I ordered methyl-violet, $\frac{1}{10}$ per cent., dropped in the eye every hour, in connection with the sulphate of atropia, and to my great delight the next day, December 12, I found the pupil dilated to more than twice its size of the day before, the congestion subsiding, the cornea clearer, and the vision sufficient to count fingers. The treatment was continued, and on the following day the patient was able to recognize a person across the room, pain was gone, redness less and pupil widely dilated. December 15, pupil wide open and vision $\frac{1}{10}$ eye fast recovering.

The methyl-violet has quite a mydriatic effect and also controls the power of accommodation to a considerable extent; though it is claimed by some that it does not affect the power of accommodation. This fact I have verified many times, by using it alone without atropia. In the above case I feel confident that the methyl-violet, from its diffusibility and germicidal effect on the pyogenic microbe, cut short the disease and so saved the eye.

I do not believe that in this case the mydriatic effect of the atropia could have obtained without the methyl violet; besides, the methyl violet controlled the irritating effect of the atropia on the cornea, and checked the keratitis.

The other case, choroido-cyclo-iritis, occurred in a young man of 25 years, dark brown eyes, A. B. Patterson, from Juniata, Neb., a station agent on the Missouri Pacific railroad. The history, as gained from the patient, was as follows: While walking down the street October 13, with a pen-knife open in my hand, I met a friend, who in play knocked my hand with the knife so that the open blade pierced my right cheek, going into the eye, and then the doctor put a suture in the eyeball and assured me that the sight would be all right (a German doctor). For about ten days the sight was very good, and then the eye began to pain and I could not bear the light, and the sight gradually diminished and the pain grew worse. An examination revealed a scar of the right cheek, lower lid and eyeball; that of the eyeball about 10 mm. long, about one-third of which extended into the cornea from the inner inferior region, near the attachment of the inferior rectus muscle. The cut of the cornea embraced the entire layers of the cornea, and evidently the blade went through the sclera and choroidal, though there was no evidence of its cutting the iris. The pupil was contracted, and the vision was not sufficient to count fingers, and photophobia intense. I ordered a 1 per cent. solution of atropia to be dropped into the eye every two hours, night and day. The second day the patient was sent to my

rooms; the mydriatic had not had the least effect. The ophthalmoscope revealed a grayish, light-colored body, with small, pale blood-vessels mounting up over it, projecting from the region of the ciliary body, and the sclera immediately exterior was swollen or bulged. There was evidently detached retina, with exudation beneath the retina. At this date I commenced the use of methyl violet, and had it dropped into the eye every hour, night and day. On the following day there was some dilation of the pupil, and less pain and soreness. December 16 I injected a 10 per cent. solution, 10 m., in the eye through the sclera, by means of the hypodermic syringe. The soreness has subsided and the pupil is more open, although the exudations are much the same.

Dr. Stilling speaks of injecting the vitreous of a rabbit without harm to the eye. My experience so far has been that the good effect from this agent is especially to be realized in inflammation of the deeper structures of the eyeball, owing probably to the great diffusibility and penetrability of the aniline, traversing almost immediately the cornea and sclera to the chambers of the eyeball, and having for its predilection the bacillus and micrococci. In ulceration of the cornea I have used it with most excellent results in the form of pomade, 1 to 200. For marginal blepharitis, or tinea tarsi, the methyl violet pomade, $\frac{1}{2}$ per cent., carefully worked into the roots of the lashes by means of a spatula, works a speedy cure. Prof. Stilling, from his bacteriological experiments, found that milk mixed with methyl violet would not sour, nor would butter become rancid; that urine even could remain in a thermostat at 32° C. for a week without putrefaction, or presenting any bacteria whatever. In fact, any substance containing a solution of methyl violet of even 1 to 32,000, is absolutely indennified. This agent acts as an antiseptic, killing the pyogenic bacteria, and from its diffusibility and non-destructiveness to tissues, it is superior to the other known antiseptics, and especially to thermo-cantery, which is so efficient a germicide, but can only be used at limited points.

In conclusion I would say that it is most important that the drug (methyl violet) be chemically pure, and free from arsenic. The article I have used I obtained from H. W. Evans & Bro., proprietors of the Diamond Drug Store, 908 Main St., Kansas City, Mo. An analysis made by our City Chemist, Dr. R. R. Hunter, and also by Dr. Claud C. Hamilton, Demonstrator of Chemistry at University Med. Col., shows no trace of arsenic.

THE WOMAN'S COMMITTEE OF THE WORLD'S CONGRESS AUXILIARY ON PHYSICIANS.—Dr. Sarah H. Stephenson, Ch'm; Drs. Julia H. Smith, Mary H. Thompson, Mary Mixer, Fannie Dickinson, Elizabeth Chapin, Sarah H. Brayton, Julia Low, W. P. MacCracken, Harriet Heyl Carey, Rachel Hickey, all of Chicago.

MEDICAL PROGRESS.

Therapeutics and Pharmacology.

THE CURABILITY OF CANCEROUS TUMORS BY INJECTIONS OF BICHLORIDE OF MERCURY.—According to the Paris correspondent of the *Medical Press and Circular* for September 17, 1890, PROFESSOR POUCEL, surgeon to the Marseilles Hospital, suggested, in 1884, that, in order to explain the production of cancer, it would be found at no distant date that the microbe of cancer would be discovered by the microscope. Since then efforts were made to prove the parasitic origin of the disease, and some pretended to have discovered the new microbe, but soon afterward the pathogenic value of the bacilli, and it was even said that the microorganism was not necessary to explain the clinical phenomena of cancer. Assuredly the transport of living cancerous cells by the veins, and above all by the lymphatics, would produce homologous tumors, wherever these cells could find favorable conditions for germination. This mechanism, although explaining the generalization of the tumor, does not clear up the cause. The bacilli of cancer, as in the case of tubercles, exact certain conditions which are transmissible in an hereditary sense, and which constitute the predisposition and the tendency. When these exist, the rapid growth of these microorganisms becomes possible, and through their contact the epithelium becomes inflamed, proliferous and deformed, characterizing cancer. It was with this idea that he undertook a series of researches at the hospital of Marseilles. He had shortly before obtained a prompt cure of a malignant pustule of a very bad form by injections of corrosive sublimate around its base, and these injections proved to him, first, that the bichloride had no ill effect on the tissues; and secondly, that it was efficacious against microbes absorbed through the lymphatics. It appeared to him, then, that it was quite rational to apply this treatment to cancer, or at least to tumors of a cancerous aspect of which the microbe (if there be one) is transmitted by the same means. Seven patients have already been submitted to this treatment, of whom the details are here given. The first was a woman without any syphilitic antecedents, whom he had treated for a long time with iodide of potassium. In the month of February, 1890, she entered the hospital for an ulcerated cancer of the right breast, which commenced ten months previously. The tumor was hard, uneven, and occupied all the mammary glands. The nipple was retracted, and the ulceration occupied the under part, giving exit to a fetid and abundant discharge. The axillary glands were as yet untouched, the tumor was free, and the general condition of the patient good. On the same day of her entry six injections (the half of an ordinary subcutaneous syringe

each time) of a solution of bichloride of mercury (1 in 1,000), were made into the most indurated points. No salivation followed, but the breast became a little inflamed. A month subsequently the woman returned, when it was found that the tumor had diminished in volume, and another series of injections were made, which were renewed four days subsequently. The decrease of the tumor was much more marked, and the fetid discharge had ceased. Unfortunately, a few days afterward, the patient was carried off by an attack of angina pectoris, to which she had been for several years subject. Two other patients were treated without success, but both of whom were very advanced in age, one of them being 81. The fourth patient was a retired officer. M. Poucel was called to him for a large phlegmon in the groin. After incision, a hard ganglion, of the size of a nut, was discovered, and as the man had had some dozen of years previously an indurated chancre, he was ordered pills of protoiodide of mercury. The tumor increased, in spite of this, rapidly, and soon attained the size of a large goose-egg. The son of the patient, a navy surgeon, was called in for consultation, and the cancerous nature of the affection was fully recognized. The first treatment was replaced by injection of the sublimate solution, a series of six every two days. At the end of three weeks all trace of the tumor had disappeared, and no return had taken place up to the present. Curious to say, the son had noticed in his own groin two small ganglions, which had dated three years back. However, about a year ago they became much more enlarged and harder, in spite of every possible treatment. Struck with the result of injections in his father's case, he tried them on himself, and for that purpose injected four half-syringefuls daily. At the end of a week these glands disappeared. A sixth case was that of a man who said that he had something wrong with his rectum, as he had often remarked a fetid, bloody discharge from the anus. Examination revealed the existence of a malignant tumor. Four injections were made daily, and in twenty days the cancer had *vanished*. The seventh and last case was that of a woman, aged 58. She was very emaciated, and presented in the left breast a hardened, nodulated tumor, about the size of a large walnut. There was no retraction of the nipple nor any affection of the ganglions. Two injections were made, and renewed eight days subsequently. Three months afterward Dr. Poucel revisited the patient, when no trace of the tumor could be found. Four more patients are at present undergoing the treatment, and a notable progress is marked in each of them. In concluding, the author says that he does not pretend that the real treatment of cancer has been found, but what he can affirm is that certain tumors of a *cancerous appearance* are susceptible of being removed by the injections in question, and

the chances, as may be conceived, are much greater when practiced at the commencement. He used the words *cancerous appearance* advisedly, as in some subjects tainted with hereditary syphilis tumors resembling cancer are observed. However, in these cases iodide of potassium is the specific, whereas it has no effect on the true cancer. Several of his patients were treated, as stated above, by that drug without result. Therefore, it may be regarded as almost certain that all the cases mentioned were real cancers.—*Pacific Med. Record*.

KOCH'S TREATMENT: GENERAL RESULTS.—In a supplement to the December number of the *Bristol Medico-Chirurgical Journal*, Drs. MARKHAM SKERRITT and BARCLAY BARON give an account of their observations of Koch's treatment during a recent visit to Berlin. They reached the German capital on Dec. 5, and stayed there until Dec. 13. They saw a very large number of cases presenting the results of treatment under the most varied conditions: at the Charité, under Leyden, Fräntzel, and Gerhard; at the Lazarus Hospital, under Langenbuch; and in the clinics of von Bergmann, B. Fraenkel, Cornet, and Levy. They also had an opportunity of seeing Koch's original cases at a demonstration given to the Hufeland Society, by Prof. Paul Guttman, at the Moabit Hospital. A full description of the method of procedure, and of the immediate effects of the injections in different forms of tuberculous disease, is given. The types of reaction are classified as follows: 1. Typical, marked reaction to small early dose, diminishing reaction to the same or even to increasing doses. 2. Increased reaction to the same or a diminished dose. 3. Prolonged or deferred reaction. 4. Effect of reaction on hectic: *a*, favorable, when there is a tendency to the substitution of the reaction type for the hectic type, and *b*, negative, when the hectic persists unaffected by reaction. 5. Fever originated by injection. These various types are illustrated by cases and charts, and the cause of the diversity of action of the remedy in different cases is discussed. With regard to the results of the treatment in tuberculous disease of bones and joints, Drs. Skerritt and Baron say that the surgeons informed them that they had never seen, under any treatment, any approach to the rapidity with which improvement took place under the injections. They themselves saw cases where sinuses in connection with the diseased bones and joints, which had long remained open in spite of all previous treatment, rapidly and completely closed. With regard to glands, it is pointed out that the usual local change is swelling and tenderness during reaction, followed by gradual diminution in size. Suppuration does not commonly occur. In the larynx the local reaction may produce increase of pain in swallowing, increase of cough and expectoration, a feeling of

dryness and constriction, greater hoarseness, perhaps aphonia, and sometimes local pain. Contrary to what the authors anticipated, they found that, as a rule, no serious obstruction to breathing was produced, and in many cases none at all. With regard to the lung, they state that little can be said as to improvement in physical signs: "in some cases *râles* and dullness are said to have diminished, and bronchial breathing to have been replaced by vesicular, but as yet time is too short to allow of decided evidence on this point." They add that Koch claims to have completely cured two phthisical patients, with one of whom they had the opportunity of speaking. They also saw a patient in whom, during three weeks' treatment, the disease markedly extended in both lungs, and a cavity formed; dyspnoea, absent before, made its appearance; bacilli, previously few in number, became numerous, and the sputum was increased in amount. One of the cases seen by them, in which there was most marked lung reaction, had been examined again and again without the detection of a single suspicious sign. They also saw many patients in whom the injection revealed in very varied parts previously unsuspected tubercle. In no case, therefore, even the least suspicious, should an injection be made without the most careful and thorough preliminary examination, and the greatest caution should be observed as to dosage. In tuberculosis of the lungs and larynx the initial dose should be one milligram, which is gradually increased, one or more "fever free" days being allowed between the injections. For purposes of diagnosis exact reliance cannot be placed upon the result of a single injection. Skeritt and Baron saw a case of established phthisis, with bacilli, in which no reaction occurred until the dose had reached one centigram, and they were informed that this was by no means a solitary instance. On the other hand, reaction occurred in patients who otherwise presented no evidence whatever of tuberculosis; as, for instance, in a girl with post-scarlatinal nephritis. They sum up as follows: "The evidence at present at our disposal warrants the conclusion that the beneficial effects of the remedy is undoubted in tuberculosis of the skin, bones, joints, glands, and throat. With regard to pulmonary phthisis, whilst there is good reason to hope that in suitable cases a most satisfactory result may be obtained from this treatment, sufficient time has not as yet elapsed to allow of the formation of any accurate estimate of its value."

—*British Medical Journal*.

TREATMENT OF Erysipelas.—An elaborate research, clinical and bacteriological, has recently been published by Professor Nussbaum's assistant, DR. JULIUS FRISLER, on the treatment of erysipelas by ichthyol, a plan which has been for some years extensively adopted in Munich.

From laboratory experiments it was evident that, though ichthyol has only a slight effect in preventing the development of staphylococci, it has a very potent deterrent influence on the multiplication of streptococci, and it is well known that it is the latter kind of bacteria that are the cause of erysipelas. The method of treatment consists mainly of rubbing a strong ichthyol ointment energetically, and for ten minutes at a time, into the affected surface and its neighborhood; ichthyol in the form of pills may also be given internally. Where there is a wound it must be very carefully disinfected, and an antiseptic dressing applied. The results of this treatment as compared with ordinary methods are embodied in several instructive tables. From these it appears that while the mean duration of the cases treated by other methods from 1880 to 1888 was about twelve days, in no single year falling below nine days, the cases treated by ichthyol from 1886 to 1888 presented a mean duration of under seven days, while in the first half of 1889 it fell to 5.6 days.—*Lancet*.

Medicine.

KOCH'S REMEDY IN TUBERCULOSIS OF THE LARYNX.—PROF. H. KRAUSE contributes the following interesting report to the *Therapeutische Monatshefte* for December, 1890. He says it is apparent that a definite result cannot be affirmed, as at the time of writing only two and one-half weeks had elapsed since beginning treatment, but the observations are of special interest at this time because of the opportunity of observing the direct effect of the remedy upon tubercular mucous membranes, which can be better seen than the effect upon lupus, for there the process is in a measure concealed by the thick crusts which form on the surface. The effect in the larynx is not as "stormy" as has been reported by some surgeons. He says nothing of the general symptoms, fever, etc., though he has noted considerable variation from those usually described.

Unquestionably a specific reaction is produced in the larynx; characterized by diffuse redness and swelling, with at first increase and later complete loss of secretion; also punctiform and diffuse hemorrhages, superficial and deep exfoliation. In ulcers the base was changed, and in favorable cases was covered by a dirty gray coat that was thrown off, leaving a clean granulating surface, that showed a marked tendency to heal. Absorption of infiltrated masses could be determined. The patients often experience a sense of constriction, and in cases presenting marked infiltration there is frequently some pain.

A cure cannot as yet be affirmed, owing to the short time that the remedy has been in use, but from its action we may look for favorable results in those cases in which the disease is not too far advanced. Especial care must be exercised in

the treatment of advanced cases, as a too rapid increase in the dose may cause very grave symptoms.

Krause mentions a case that had been under observation for eight weeks, in the last two and one-half of which the treatment had been with Koch's remedy. A decided change for the worse was noticed in this patient, which the writer is inclined to attribute to the fact that the limitations of the remedy have not been determined, and in consequence it has not been decided at what time surgical interference is necessary.

The writer describes the following case: A young woman, well nourished, presented herself at the polyclinic. The right lung was involved, the mucous membrane of the larynx presented a diffuse swelling, so extensive as to interfere with deglutition. The epiglottis was three times its normal size. Lactic acid and cretting were employed, and the patient improved so that swallowing was easy and the cavity of the larynx could be seen, showing the gray ulcerations left by the caustic. In this stage Koch's remedy was employed. Twenty-four hours after the injection the secretion disappeared, the infiltrated ligaments and epiglottis decreased. A few days later the swelling increased, but a gray coating was soon cast off, leaving a clean granulating surface. The later progress of the case with an increase in the dose, showed similar results, excepting that the action was more vigorous, and left deep ulcerating patches.

Another case was that of a young man who had in the posterior wall of the larynx a small tumor, that after 1 milligram of the remedy was thrown off completely, leaving a clean granulating surface that soon healed.

The writer contributes several similar cases, showing the more or less favorable action of the remedy.

NOCTURNAL ENURESIS TREATED BY POSTURE.

—DR. VAN TRENTON, of La Hague, in a paper read before the Berlin Congress, offered the simplest explanation and treatment of nocturnal enuresis that has lately been presented. His theory is that in some children there is an insufficiency of the sphincter vesicæ, which permits the urine to come in contact with the upper urethra, and this in turn, by reflex action, causes the detrusor urinæ to act. He argues that it cannot be that this trouble is due to the impression of distension of the walls of the bladder, because not a few children wet the bed within a period, for example two hours, after going to bed that is too brief to have the bladder in a distended condition. His plan of treatment undertakes to prevent the urine from flowing into the urethra, by raising the foot of the bed. He has made fourteen cures by this method, with the two added precautions of having the child empty the bladder just before getting

into bed, and of allowing no drink to be taken by the patient for some while before bedtime.—*Annals of Gynecology.*

OBSTETRICS AND DISEASES OF WOMEN.

LAPAROTOMY. — M. C. JACOBS (*Bulletins et Mémoires de la Société Obstétricale et Gynécologique de Paris, Séance du 11 Décembre, 1890*) reports a series of fifty laparotomies with only three deaths, or a mortality of but 6 per cent.

Five operations were for uterine fibromas, including two hysterectomies, with extra-peritoneal treatment of the pedicle, recovery; one hysterectomy, in which the pedicle was dropped with its elastic ligature; this was followed by inflammation necessitating two consecutive laparotomies, with ultimate recovery; one double castration, cure; and two ablations of pedunculated fibroids, attended with recovery. Three operations were performed for tuberculosis of the peritoneum, with three recoveries from the operation. The writer justly observes that only the lapse of considerable time would permit one to say that there was complete recovery. Twenty-one operations were performed for salpingitis, eighteen with castration and ablation of the diseased tubes. The writer reports excellent results in these cases. In unilateral purulent salpingitis the ablation of one tube and ovary was sufficient, while in the catarrhal and interstitial forms the removal of both tubes and ovaries is indicated. Two deaths are reported in this group, one from septic peritonitis the other from pulmonary congestion.

Dr. Jacobs reports five exploratory laparotomies, but only one of these can be classed strictly under this tentative procedure, the abdomen being opened for a phantom tumor; another case was one in which the abdomen was opened in consequence of a septic accident, following a previous laparotomy; in another case a purulent foyer was found in the upper portion of the cicatrix. Eight ovariectomies with eight recoveries are reported, two of them were for cysts of the broad ligament. Five hysterectomies were performed for painful prolapse and retroflexions. Sufficient time has not elapsed to permit a definite answer as to results.

THE INFLUENCE OF ARTIFICIAL RESPIRATION ON THE HEART OF THE NEWLY-BORN. — DR. W. E. FOREST read a paper in the Section in Pediatrics, New York Academy of Medicine, Dec. 11, 1890, with this title, based upon three interesting cases. In the first, after prolonged labor, the child was apparently dead. No pulsation of the heart could be detected by the hand, but by the ear it was found to be beating sixty a minute. After artificial respiration for fifteen minutes the pulsations increased to 120, but rapidly decreased in number when the child was left for a few minutes to itself. This was repeated many times with a similar result. After an hour and forty-five minutes the heart continued to beat, but as

no effort at respiration had been made by the child, the case was abandoned. The second case lived, the result of artificial respiration being invariably to increase the cardiac pulsations. In the third case artificial respiration was continued an hour and forty minutes before the child could breathe.

The method employed is in some respects entirely new. The child is placed in a pail of hot water to maintain the vital heat. This the author believes is a point of great importance. The head is then grasped by the hand and thrown backward so as to throw the vertebræ of the neck forward. The hands are drawn up and pressed against the chest. This compresses the œsophagus between the larynx and vertebræ, and at the same time the mouth opens. The physician then blows strongly into the mouth of the child. The œsophagus thus compressed prevents the entrance of air into the stomach. The head is then thrown forward, and the arms brought down to the side so as to expel the air from the lungs.

The points of especial importance are the use of the hot bath to maintain the vital heat; the use of the ear to detect the cardiac pulsations which could not be felt by the hand; the necessity of long-continued effort if pulsations can be heard; and the peculiar method of compressing the œsophagus.

Dr. W. H. Thompson, strongly advocated the hot bath. The method of artificial respiration was ingenious, and certainly showed that the lungs had been inflated.

SEXUPLE PREGNANCY.—VASALLI (*Rassegna di Scienze Med.*) reports the case of a woman who in the fourth month of pregnancy reached a size equal to that of term. She was taken with pains and in the course of six hours was delivered of six feti. Their combined weight equalled 1,730 grams, the largest weighing 305 and the smallest 250 grams. Their length varied from 22 to 26 cm. The single placenta was large, adherent, and had to be removed piecemeal. It presented six distinct fetal sacs.

Bacteriology.

MICROBE OF EPIDEMIC CEREBRO-SPINAL MENINGITIS.—At the present time very few opportunities occur of studying epidemic cerebro-spinal meningitis. DR. BONOME has had such an opportunity, and made careful investigations as regards the anatomy and etiology of this disease. The outbreak occurred near Padua. His conclusions, together with an account of his experiments, are published in Ziegler's *Beiträge zur pathologische Anatomie und zur allgemeine Pathologie*. Dr. Bonome was able to examine thoroughly the bodies of five patients who had died from the disease, and the meningeal exudation from a sixth. In addition, in several other cases the blood and catarrhal secretions from the throat

and nasal cavities were submitted to investigation. He succeeded in isolating from the exudations of the cerebro-spinal meninges, and from hæmorrhagic collections in the lungs, a streptococcus, which did not, however, grow readily on artificial media, and when so cultivated, or after being preserved in a dry state, soon lost its pathogenic characters. In white mice and rabbits the microorganism produced the same effects as those brought about by injections of the pneumococcus or meningococcus, fibrinous inflammations being induced, whilst in guinea pigs and dogs the microorganism scarcely reacted at all to the pure cultures. This streptococcus found by Dr. Bonome differs from the pneumococcus and meningococcus again in the ball-shaped appearance of the colonies on agar-agar plate cultivations, in its inability to grow on blood serum, and in the difficulty which is experienced in carrying the cultures through five or six generations. Also it fails to produce true septicæmia in white mice; and when rabbits are inoculated, the micrococci obtained from the blood are arranged in chains surrounded by a capsule, and the same forms are obtained from the gelatinous transudation met with in mice, guinea pigs, and dogs which have been artificially infected with the disease. The streptococcus, again, is distinguished from the streptococcus of erysipelas by its action on animals and by its failure to grow on gelatine and blood-serum, and also by the appearance of the colonies on agar-agar plates. In contrast with other microorganisms which are morphological analogues many differences can be made out. Thus, it differs from the streptococcus pyogenes and from the septic streptococcus found in earth by Nicolaier and Guarnieri; also it can be clearly distinguished from the streptococcus found by Loeffler in cases of diphtheria, and from the organism found by Weichselbaum in some cases of pneumonia. After careful consideration of all the points in connection with this epidemic at Padua, and the results of his bacteriological examinations, Dr. Bonome claims that he has substantiated the existence of the microbe of epidemic cerebro-spinal meningitis.—*Lancet*.

PATHOGENESIS OF TETANUS.—FABER (*Berliner Klin. Wochenschr.*) has separated by filtration, from pure cultures of virulent tetanus bacilli, a substance that is wholly free from germs, and yet when it is injected into animals, either in the cellular tissue or blood, it produces the clinical picture of tetanus. There seems to be a certain latent period, before the production of the symptoms, that varies with the virulence of the culture from which the extract is prepared. When injected into the blood it produces general convulsions, when into the cellular tissue these are associated with local convulsions. No specific immunity could be determined as a result of the injections.

SINGLE COPIES.....10 CENTS.

Subscription may begin at any time. The safest mode of remittance is by postal or express money order, drawn to the order of THE JOURNAL. When neither is accessible, remittances may be made at the risk of the publishers, by forwarding in REGISTERED letters.

Address

JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,

No. 68 WABASH AVE.,

CHICAGO, ILLINOIS.

All members of the Association should send their Annual Dues to the Treasurer, Richard J. Dunglison, M.D., Lock Box 1274, Philadelphia, Pa.

LONDON OFFICE, 57 AND 59 LUDGATE HILL.

SATURDAY, FEBRUARY 25, 1891.

SECTION MEETINGS OF THE ASSOCIATION.

The real success of the Association meeting depends mainly upon the work done in the Sections. The general addresses vary widely, and although they often present very excellent discussions and résumés of our present knowledge, still they are not presumed to reflect the best scientific work, but to deal in a general and popular way with medical interests generally. The officers of the Sections are, after all, more influential in directing medical progress. They should not leave the topics altogether to the chance of volunteers to prepare and read papers; nor after inviting and receiving a dozen or more papers on widely differing topics, and finding it impossible to group them in any natural order, should they proceed to serve them up on the time plan in the order of their reception. The officers of each Section should select one or more general topics that have a broad interest to the whole profession, then invite several leading men to discuss the different phases of the subject. After this voluntary papers may be admitted. In this way the listener could get some general idea of the views of the best authorities, in some of the different fields of medicine.

More important still is the method of presenting papers. Each reader should remember that his listener is a practical man, who comes for a practical purpose of enlarging his knowledge of science; also that his medical position or reputation is of little moment to the hearer. The hearer, like the Athenian of old, comes to hear something new;

or to compare his knowledge with others. First of all the writer of a paper should be convinced that he has some new fact to communicate; some new view of the etiology, pathology or therapeutics of some disease; or some new effect of a medicine; or some fact that has not been mentioned before. Then state this fact in the briefest way possible. If it be relating to pneumonia, he reflects on the intelligence of his audience by giving the history and pathology of this disease, and the many views of different authors, when he merely wants to call attention to a new remedy and method of cure. If he has made a discovery in the pathology of diphtheria, the history and views of others of the pathology is an assumption that his audience are first-course students in medicine, and can not appreciate his views unless the entire history is given. If it is on a surgical subject, or any other branch of the practice, it is always in bad taste to go over in detail general principles as laid down in any text-book. It is also very suspicious for any writer to load down his topic with references to foreign authorities, which the average reader can not verify, or even to quote largely from home writers, and close up with a ponderous list of references. If he is writing a book or prize essay, it may not be noticeable, but for a paper to be read at the Association meeting, it should not be. All the listener wants are the writer's conclusions and the facts upon which they are based. He will listen cheerfully to a full elucidation of these, but turn away wearied when the writer falls back to describe well known facts.

A paper for the Association should only be exhaustive along some new unknown range of study, and even then the writer will be praised for giving his conclusions, and refer the listener to a printed copy when it appears in the Association Journal. THE JOURNAL, in not a few instances, has suffered from the space given to long papers, which were but a mere repetition of what could be found in every text-book. These papers were read before some Section, and their publication was inevitable. The writers were merely publishing their own weakness, and THE JOURNAL can not be made responsible. The elevation of the tone and character of THE JOURNAL will largely depend on the writers and readers of papers at the Association meetings. Editors may write well, and make selections of the best current literature, but if the best half of THE JOURNAL is

filled with heavy padded, pedantic and text-book papers, their efforts are sadly neutralized.

Is it not true that journalistic literature is unfortunately loaded down, in all sections of the country, with papers made up from text-books, that suggest nothing, or teach nothing, that has not been known before? THE JOURNAL has the same experience as others, but, unlike them, it can address its writers in advance. At the coming meeting at Washington over a hundred papers will be presented and read. Each writer will always represent himself more than the topic he discusses. If he has anything new to communicate, it will not be lost in faults of presentation, or of style of writing. If he has nothing new, all the elegant flow of words, and learned references to vast libraries can never give it life or vitality. Each writer should remember that he can not in any single paper of any reasonable length exhaust his topic, or even convey a complete general impression of the entire subject. This is very evident in the attempts of really expert men to give reports of the progress of science in any one department, which is always imperfect, and becomes more so every year, for the reason that the progress of medicine is so rapid and expansive that no one man can present any complete picture of even one department. Each writer should remember that his personal views and opinions are only valuable when they are sustained by real or assumed facts, which his audience would like to hear, so as to form an opinion for themselves.

The facts of medicine are like those of astronomy, always open to a marked personal equation which is a source of error that needs constant correction. A writer may be very positive in his conclusions, but a study and comparison by others of the same topic fail to sustain him; hence it is dangerous to urge the completeness and accuracy of any facts beyond all others. Each writer should never forget that the Association and its meeting represents the science of medicine in this country. Papers which have been praised in his local society come before a different audience in the Section meetings. Nothing can be greater injustice personally and to the Society than careless, confused egotistical papers.

THE JOURNAL particularly urges all writers who are to take part in the coming meeting to present their best work, in the best manner. It

would also urge the officers of each Section to discriminate and arrange papers that are offered, and advise writers frankly as to the merits of their papers. Brevity and condensation are the practical needs of the medical public. While the general character of the papers read at the Association meetings have been steadily improving, the demand each year is for broader more thorough scientific discussions. The theories and conclusions of last year can not always be trusted to-day. The progress of medical science is rapid and intense, and the aspect of many supposed facts have changed materially. A repetition of last year's papers, unless fortified by some new evidence and new views, are open to grave criticisms. Extraordinary results from the application of remedies or methods of treatment bring the writer into a centre of suspicious criticism. All such papers need to be grouped with great care and exactness.

Finally, THE JOURNAL, upon whom much of the criticism falls for bringing to light the varied papers which are read before the Association, would remind all the coming writers, that the more accurately and scientifically they present their papers, the greater the success of the meeting. An *ideal* journal can only be made by embodying the high scientific ideals of the writers in its pages.

The most practical fields of work are observing, grouping and comparing real and supposed facts, not to discover their full meaning, but their possible practical relation. This is the spirit and purpose of the Association, and the responsibility and scientific success of the coming meeting will turn on the recognition of this fact.

The members of the Association look to the officers of the Sections and the writers to make the coming meeting superior to all others. This will be merely along the line of all science in evolutionary growth.

DIET IN BRIGHT'S DISEASE.

LÉPINE, in a paper before the International Medical Congress, on "The Treatment of Bright's Disease," maintained that the chief indication was the prevention of uremia. With this end in view he laid special stress upon the importance of lessening nitrogenous food to a point where tissue waste would be just balanced, which he placed at about 80 grams of albumen daily for

the average adult. In practice he thinks the best results will be achieved by a milk diet, to which a certain proportion of carbo-hydrates are added, as the nitrogenized constituents are present in too great relative proportion in milk.

If we adopt the view that "uræmia" is dependent upon an excess of urea in the blood (WILLIS), or of carbonate of ammonia (FRIEDRICH), or of creatin and creatinine (OPPLER, PERLS and ZALESKY), it is at once apparent that a lessening of the proteids of the diet would decrease the amount of these nitrogen-containing substances, in the blood.

Unfortunately, the process is not quite as simple as these views would lead us to think. In Bright's disease there are profound changes in the blood, and one writer, REES, asserts that the symptoms of uræmia are caused by tenuity of the blood and increased vascular pressure. If this is true, it is possible that a marked lessening in the proteids of the diet might aggravate the very condition it was intended to relieve.

Unquestionably a proper regulation of the diet, so as to include only a due proportion of nitrogenous food, is of the utmost importance, particularly in the early stage of Bright's disease, and nephritis generally. In this stage the kidney should be placed physiologically at rest as far as possible. Whether in the later stages, when uræmic symptoms may be looked for, and marked changes in the blood and vascular pressure are present, much is to be hoped for from a mere lessening of nitrogenous food, is still a matter of grave doubt, and in the light of the very uncertain pathology of uræmia, perhaps hardly justifiable.

DIGITAL SYPHILIS OF MEDICAL PRACTITIONERS.

A correspondent in the *Southern Medical Record*, January, quotes DR. FESSENDEN N. OTIS, of New York, in regard to the occurrence of an intractable sore on the finger of a surgeon or accoucheur due to syphilis. Whenever a sluggish lesion in this situation presents itself, he always suspects specific infection, and narrates a case illustrative of some of the difficulties that surround a conclusive diagnosis. About two years ago, he chanced to be at Lakewood, where he saw a gentleman going about with his fingers wrapped up in a handkerchief. The latter gentleman was a

surgeon of large practice in a Western city, and having been introduced to DR. OTIS, showed him a finger that had been troublesome for some months, dating back to the time of a certain surgical operation, in the course of which his finger had been cut with the knife. The operation was an ordinary hare lip operation, on a young German girl, for removal of a lesion that was regarded as cancer of the lip. A sore soon after made its appearance about the nail, and became troublesome. Recognizing the possibility of causal relations between this sore and the lip lesion of the German girl, the finger was laid open down to the bone and scraped, dressed antiseptically and put in a plaster bandage. He had at the time a suspicious eruption, and some of the glands were enlarged, but not the epitrochlear. He was put on mixed treatment, and as he was quite unable to do any professional work, was advised to go abroad. He went to England, and while there consulted SIR HENRY THOMPSON. The latter examined the patient, and his finger and eruption, carefully, and denied the existence of syphilis in the case; he advised him to throw away his medicines and go home. He returned to this country and related the circumstances of his visit to the London surgeon to DR. OTIS, who strongly recommended him to hunt up the German girl upon whom he had operated. He did so, and subsequently reported that she had developed unmistakable symptoms of secondary syphilis.

At the Hunterian Society, recently, MR. C. J. SYMONDS stated that he had known of as many as five medical men with genuine Hunterian chancre of the finger, acquired in obstetric practice. He has known amputation of the affected finger to be performed where the joint was much endangered; but he had not yet found this measure needful. If the sore be thoroughly scraped and cauterized with acid nitrate of mercury, the bone and the joint will most likely be saved.

HYDROCYANIC ACID ANTIDOTAL TO TUBERCULOSIS.

SCHRÖTTER, of the University of Vienna, has announced to his colleagues of the Society of Physicians that he has made a partial investigation regarding the alleged discovery of the immunity of a certain class of artisans in Austria against tuberculosis, and he has come to the conclusion that that disease is very rare in those

workshops where the cyan-metals, as they are called, cyan-gold and cyan-silver, are employed. He holds that the hydrocyanic acid is the efficient element in these chemicals, and that he has data sufficient to warrant the systematic trial of that agent as a bactericide in tuberculosis. Incidentally, it may be remarked that he has found that not only is it a very rare occurrence, among the workmen of the class referred to, for pulmonary disease to attack one of them, but also it is often remarked that those who come from other places and other works with incipient troubles have been benefited, and some of them have been entirely cured, at least so far as the testimony of the workmen themselves went.

There are several large factories in Southern Austria where fine metallic wares are made, and in the finishing of them the cyan-metals dissolved in the cyanide of potassium are required to be used in order to galvanize them in silver or gold, and the atmosphere of these factories is more or less heavily charged with the complex vapors given off from the vats and chambers; the assumption being made, however, that the potential chemical is the acid, and not the precious metals that are combined with it.

EDITORIAL NOTES.

THE MEDICAL SOCIETY OF THE STATE OF TENNESSEE.—The annual meeting of this State organization will convene at Nashville on April 14, and will be in session for three days. The officers of the Society have made ample provisions for a most successful meeting. They advise us that an unusually full list of valuable papers is promised by men who will not fail to sustain their well established reputations both as writers and speakers. The home of the President of our Association will not only honor its State by this meeting of its representative men, but we look to Tennessee for a strong reinforcement to the ranks of the American Medical Association at its next annual meeting.

CENTRAL-ZEITUNG FÜR DAS KOCH'SCHE HEILVERFAHREN is the title of a new journal devoted especially to progress in the treatment of tuberculosis and other infectious diseases. It appears on the first and sixteenth of each month. The current issue, No. 3, contains the article of Prof. Virchow on the changes produced in internal or-

gans by injections of Koch's lymph, a continued article from the pen of Dr. Kammerer on the experience with the same remedy in Vienna, also von Gossler's regulations to prevent the spread of tuberculosis. In addition there is a *résumé* of other publications. It cannot be said of modern science, especially the German, that its light is under a bushel. The establishment of a new journal to exploit a discovery only a few weeks old, argues most praiseworthy activity.

CORRECTION.—The annual meeting of the Medical Society of the Missouri Valley will convene at Omaha, Neb., March 19 instead of March 17, as previously announced in *THE JOURNAL*.

A HEALTHFUL SUBTROPICAL CLIMATE.—The English journals evince a feeling of exultation in speaking of the comparatively salubrious sections of the British sphere of influence, in east Central Africa, some parts of which lie directly under the equator. In contrast with some more southerly points occupied by the Germans, this English territory, even on the coast line, has a climate that is both more endurable to white colonists and more healthful. Even in the hot season they claim that it is cooler than it is five degrees farther south.

HARPER HOSPITAL, DETROIT.—Dr. Heneage Gibbs, Professor of Pathology at the University of Michigan, has been appointed consulting pathologist to the Harper Hospital, Detroit. This appointment will enable Dr. Gibbs to coöperate freely with his colleague, Dr. Shurly, in their joint researches concerning the nature and treatment of pulmonary tuberculosis, which are about to be carried out on a larger scale than heretofore.

ACCIDENT TO VON BERGMANN.—An injury sustained by Professor von Bergmann in the course of professional duty, has compelled him to take a temporary leave of absence from all official work. The wound involved one of the fingers of the right hand, and at first was not considered to be serious, but it has rendered repeated slight operations necessary. The professor has been and is still confined to his room, and will probably have to carry his hand in a sling for some time to come.

PATIENTS undergoing the "lymph" treatment at Chicago Presbyterian Hospital show no very decided improvement up to the present time.

MEDICAL ITEMS.

ACCIDENT TO PROF. BERGMANN.—It is said that Prof. Bergmann has had the second finger of his right hand amputated on account of threatened blood poisoning from an operation on a lupus patient who was undergoing the Koch treatment.

THE MINNESOTA PRACTICE ACT.—The operation of the Minnesota Medical Practice Act has reduced the ratio of physicians, from one to six hundred and fifty, to one in twelve hundred and fifty. During the past three years two hundred and five candidates presented themselves for examination, seventy-seven of whom were rejected.

THE TRICKS OF NEW ORLEANS MILKMEN.—It is said to be a common practice in New Orleans for milkmen to renew the creamy appearance of skimmed and watered milk by the addition of condensed milk from cans. If such is the case its importance at once demands the attention of the health authorities, or else all New Orleans infants should be denied the preparation.

UNIQUE IRISH DECISION.—The *Boston Medical and Surgical Journal* repeats from foreign sources as a true story, a remarkable verdict rendered two or three weeks ago in Ireland, growing out of the railroad calamity that took place near Armagh. The plaintiff, a woman who had been injured, sued first for damages to herself—she had been bruised and shaken and caused to come to premature childbirth, with much risk, anxiety and suffering—and the jury gave her £800. Next she sued on behalf of her baby, which has been from the time of premature delivery puny and deformed, and not expected long to survive. The jury awarded the infant nothing, for the reasons that the company never sold a fare to include that baby, and in fact the company had no knowledge that the baby was on the train. Therefore according to law no responsibility attached to the company in respect of that sur-reptitious passenger.

THE AMERICAN ELECTRO-THERAPEUTIC ASSOCIATION, was organized on the 22d of January, 1891, at the Academy of Medicine, No. 17 West 43d St., New York, by the adoption of a Constitution and By-Laws, and the election of the following officers: President, G. Betton Massey, M.D., Philadelphia; Vice-Presidents, William James Mortou, M.D., and Augustin H. Goelet,

M.D., New York; Secretary, William H. Walling, M.D., Philadelphia; Treasurer, Geo. H. Rohé, M.D., Baltimore.

Executive Council.—Horatio R. Bigelow, M.D., Philadelphia; Franklin H. Martin, M.D., Chicago; W. F. Hutchinson, M.D., Providence, R. I.; Frederic Peterson, M.D., New York; and Chauncey D. Palmer, M.D., Cincinnati, O.

The object of the Association, as stated in Article Second of the Constitution is, "The cultivation and promotion of knowledge in whatever relates to the application of electricity in medicine and surgery." The Association starts with a strong and vigorous membership, and has every prospect of a most useful and successful career. The next meeting will be held in Philadelphia, in September, of this year. Wm. H. Walling, M.D., Secretary, 2005 Arch St., Philadelphia, Pa.

CHLORAL HYDRATE IN EPILEPTIFORM CONVULSIONS.—An Irish physician, Dr. W. Ashley Cummins, reports a case of almost continuous epileptiform convulsions opposing alike the influence of nitrite of amyl, hyoscyanine, potassium bromide, chloroform, nitro-glycerine and bichloride of soda, but which finally succumbed to enemata of chloral hydrate, gr. xxx, every three hours.

DR. N. H. KIMBALL, a physician well known in Southern Michigan, died at his home at Adrian, Mich., recently.

THE ART OF CATCHING COLD.—The *Provincial Medical Journal* has an article in a late issue entitled: "The Art of Catching Cold; by a Professional Failure." Truly such a heading should not fail of attracting a generous number of readers.

THE KOCH TREATMENT.—General medical literature (periodical) still teems with papers, lectures, and reports of the Koch treatment; although it is believed that the first enthusiasm is subsiding to a more conservative estimation of the cases receiving attention in the home hospitals. The true merits and proper application of Prof. Koch's discovery, are yet to be determined.

THE TIME TO RECORD DAILY TEMPERATURE.—Prof. Da Costa considers that in important cases the daily temperature should be recorded close to the hours of 7 A.M. and 7 P.M. Where only one observation can be taken, it should come near the evening hour.

TOPICS OF THE WEEK.

THE MORPHOLOGY, CULTIVATION AND TOXIC PRODUCTS OF THE TUBERCLE BACILLUS.

At the meeting of the Pathological Society of London, held February 3, 1891, Dr. Edgar M. Crookshank presented a paper of remarkable value upon the above subjects. He gave a series of demonstrations of the morphological varieties of the tubercle bacilli, comparing those in the tuberculosis of various animals, such as the horse, pig and cat; and of birds, such as the fowl, guinea fowl, pheasant and ostrich. It is found that in these, minute morphological differences can be discerned, showing that, within certain limits, the morphology of the bacillus varies with its environments, and that certain modifications are dependent upon methods of culture. He enters quite fully into a description of his methods, and then deals at length with the toxic products, giving in particular the results of his own investigations.

The London *Lancet*, commenting upon the paper of Dr. Crookshank, gives a brief outline of the conclusions to be derived therefrom, and from the discussions which followed its presentation, in the following words:

It is evident that, although chemists, bacteriologists, and pathologists are working to a common end, each emphasizes somewhat different points. On the one hand, we have the bacteriologists taking up rather the botanical aspect, cultivating the tubercle bacillus in different media, and retarding or increasing the rate of growth and development by the addition of certain substances. They, in fact, study the organism as a saprophyte, and are contributing most remarkable facts to our knowledge of the history of the organism outside the body. When, however, on the other hand, the chemist comes to consider the action of the organism as a parasite, the facts obtained by the botanist are for the moment of comparatively little value, as Dr. Sidney Martin indicated. All the knowledge that has yet been obtained in connection with the action of the organism on the animal economy points to the fact that they do not act any in way except through their poisonous products. These products are derived entirely from the breaking down of albuminoid substances. It may be, of course, that some of them are only one or two removes from the higher albumens; whilst others may be looked upon as the later products of the decomposition of this same material by special organisms. It is evident therefore that the specific toxic functions of a parasitic organism can only be brought into full play when it is placed in a medium that contains sufficient albuminoid material on which the organism may act to produce the specific material. Of course, it may be objected to Dr. Martin's statement that alkali albumen (to which he would add the special salts required) is probably one of the best nutrient media for the growth of the tubercle bacillus in all its strength, and that alkali albumen does not occur as such in the body, just as fibrin does not; but to this may be answered that, although fibrin does not occur as such, the constant elements of which it is composed are undoubtedly present, and that the organism has therefore only a little more or a little less work to do to obtain the same results.

To the physician, however, who has to deal with disease in both its etiological and pathological aspects, something more than either the chemist or the bacteriologist tells him is necessary. He has not only to study the conditions under which the organism is developed outside the body, the method of invasion of the tissues by the tubercle bacillus, the local changes to which it gives rise, and the general or constitutional symptoms that result, but he has also, if possible, to trace the phylogenetic relations of the organism to see how its specific activity may be modified, and to apply the results of the experience already gained to the improvements of methods of treatment, whether by inoculation or by other means; in fact, nothing must escape his notice, and no means of increasing his knowledge of any phase of the life of the organisms that produce disease can be neglected or cast aside as unimportant. The tubercle bacillus within the next year or two will receive more attention than any other of the microorganisms. It will be studied by competent and incompetent observers; the most contradictory results will be obtained; we shall be told that the tubercle bacillus forms enzymes, albumoses, tox-albumens and ptomaines. It will be argued that its growth takes place most luxuriantly under certain conditions, and that certain other conditions are absolutely inconsistent with any growth at all. Let all such very positive statements be taken with reserve, for it is becoming evident that if care is taken to make a transition by sufficiently easy stages, tubercle bacilli, like many other organisms, may be cultivated under very different conditions as regards soil, temperature, etc., and that consequently the resulting products are equally varied. Thanks to the younger workers in physiological chemistry in this country, a new school is gradually being formed, and it is evident that much more accurate and valuable data than we have hitherto possessed are being gradually accumulated. We may, in fact, look forward to a comparatively new development of bacteriological science as coming within the range of practical medicine—a development that, in its bearings on medical practice, must have most far-reaching results.

FACTA NON VERBA.

We have received communications from several quarters pointing out what is, indeed, only too apparent—that the scientific and public interest in the remedy for tuberculosis introduced by Dr. Koch is being utilized pretty extensively by many who should know better, for purposes and by methods which cannot easily be differentiated from those of public and personal advertisement. This is obviously true, both here and abroad. Some allowance must, of course, be made for the exceptional nature of the circumstances, and the intense public interest aroused all over the world by the pronouncement of this distinguished observer of a probable cure for a disease which has so long been an almost irremediable scourge of the human race, and the far-reaching vista which this announcement opened up in many directions. It is more than time, however, that means should be taken to abate the proceedings referred to, and the good sense of physicians throughout the world will lead

them to refer to the ordinary rules regulating conduct in the discussion of remedies *sub judice*, and the avoidance of anything savoring of personal advertisement. It is sufficiently clear that much time must elapse, with rigorous observation during that lengthened period, before conclusions can be safely drawn either as to the sphere of utility or the complicated perils of the process. Meantime the professional tribunals—the societies, lecture-rooms and journals—of the profession are those which should be sought, rather than the public verdict on a subject on which only the technically skilled and educated can form a judgment. The excitement which so momentous an issue could not fail to raise has led to much premature proceeding, and until a mature judgment can be attained, silent work will show to advantage over hasty public utterance.—*British Medical Journal*.

PROFESSORS VIRCHOW AND HELMHOLTZ

Our Berlin correspondent writes: Professor Rudolf Virchow's 70th birthday will be celebrated with due honors on October 13 of this year. Professor Waldeyer, Drs. W. Reiss, Bartels, Langerhaus, Ad. Meyer, and Professor B. Fraenkel have issued a circular inviting friends and admirers of the great pathological anatomist to subscribe to a gift of honor, which is to take the shape of a golden portrait medal (about 19 centimeters in diameter). We understand that a committee is in course of formation in London under the presidency of Sir James Paget, to enable his English admirers to participate in the compliment. Professor R. von Helmholtz's 70th birthday will also fall this year on August 30, and will, no doubt, be celebrated with the honors so eminently his due.—*British Medical Journal*.

A LEPROUS VILLAGE.

M. Boinet states that leprosy is rare in the mountainous parts of Tonquin, but frequent in the delta, and that the lepers live in villages situated in the environs of some large populous centres. The most curious of these is situated two kilometres from the French concession of Hanoi, the inhabitants numbering 400, almost one-half of whom are affected with leprosy, the remainder being composed of infirm persons and beggars. According to the statements of the chiefs of the village, leprosy is often transmitted hereditarily. Eighty to ninety per cent. of the children of lepers contract the disease, which usually appears for the first time about the eleventh year, and rarely develops after the age of 40, exceptionally before the age of three years. Boinet traced heredity only in 15 out of 80 observations; but he recognizes that these figures are not sufficient, for lepers who come from the neighboring villages do not readily acknowledge heredity, and reliable information is impossible. Anaesthetic leprosy is more often hereditary than tubercular leprosy. Boinet concludes that heredity is of slight importance in the development of leprosy, many cases called hereditary being only examples of "heredo-contagion" or simple contagion, the proof of which lies in the late development of leprosy in the children of lepers and in their relative immunity when removed in time

from their parents. With regard to this, Boinet states that certain lepers whose resources permit them to do so send their children from the lazaretto as soon as they are weaned, to prevent their contracting leprosy. The lepers of Hanoi doubt the contagiousness of leprosy, and the chiefs of the village, who are interested in denying it, affirm that there has not been a single case of contagion. Boinet, however, in 80 observations made by him found the possibility of contagion in 51, and in 5 of these contagion appeared clear. Boinet gives particulars regarding cultivations of the bacillus lepræ on agar-agar. If his experiments are accurate, it would appear that the bacillus lepræ develops in stagnant water and in rivers, which he thinks would explain the fact that there are seen at Tonquin leprosy foci along the course of small rivulets.—*Lancet*.

THE SIEGE OF MAYTENCE

The *Archives of Military Medicine* recently gave an interesting account of the medical history of this siege in 1793. The medical officer in charge of the hospital says: "On the 11th of April there was a dreadful cannonade. Amongst the number brought us with enormous wounds—and the number was not inconsiderable in less than an hour, eight for various amputations—was a little volunteer with great courage, although suffering terribly. I ordered that he should be addressed while I went round the ward to glance at the various operations which the assistant surgeons were performing. Returning to him with Citizen Rivière, who was to perform the operation, we perceived an enormous lower limb, enormous from the unusual amount of swelling. Manipulating the limb, we came across a hard swelling, which we took to be caused by a grapeshot ball lodged in the limb. Our astonishment was great when we found that an incision of five or six fingers' breadth was insufficient to extract this enormous foreign body, which, on being finally got out, turned out to be a Prussian ball weighing no less than thirteen pounds! How could a mass of this size have just the amount of force necessary to lodge in a thigh and not pass through it! This problem I leave to natural philosophers, but I admit it to be almost necessary to have seen such things to believe them. Of course there was nothing for it but to operate on this poor fellow or leave him to certain death; we therefore amputated high up. When we had finished he asked if it was done, and on being told that it was, he cried out loudly, 'Long live the nation.' Anaesthetics had not then been seen, it must be remembered. On another occasion the firing of a mine caused a tremendous explosion, which shook the hospital building terribly. At that moment I was engaged in amputating the limb of a soldier. As I was sawing the bone amidst the general confusion caused by the first shock, a second occurred which brought down the whole of a glass skylight over the patient and myself. Not knowing whence all the glass came, I asked those standing around what was the matter. The patient overheard me, and said, 'Go on, don't alarm yourself, you will see plenty of this kind of thing.' When I had finished the operation he cried, 'Vive la République!'"—*Paris Correspondence, Lancet*.

SOCIETY PROCEEDINGS.

St. Louis Medical Society.

Stated Meeting, Saturday Evening, Feb. 7, 1891.

THE PRESIDENT, L. BREMER, M.D., IN THE CHAIR.

VESICO-VAGINAL FISTULÆ.

DR. BOND said: The subject of vesico-vaginal fistulæ is a subject that has not lately received much attention by discussion or by the pen, and it is an affection which to the sufferer is almost intolerable. The condition of a woman with water constantly escaping from the bladder through the vagina occasions a degree of discomfort almost inexpressible; considering the great difficulty that in many cases is encountered in relieving this condition, it is important that those gentlemen who attempt to operate for the cure of vesico-vaginal fistulæ should have a clear appreciation of special conditions that prohibit or prevent the best results.

During the International Congress that met at Washington City special attention was directed to the influence of constricting bands in the vagina in compromising successful results, by a very elaborate paper read by Dr. N. Bozeman, of New York City, on this subject. In it he emphasized the necessity of dilatation by means of sponges inclosed in rubber bags and introduced into the vagina, and also the necessity of dividing any cicatricial bands that distorted the parts and prevented ready access to the fistula on which he desired to operate; or that might produce undue tension upon the sutures after they were placed.

An illustration of the value of those instructions was found in the case of a lady commended to him, who for several years had suffered from a vesico-vaginal fistula resulting from a protracted labor. She had already been operated upon, but unsuccessfully. The fistula was an inch and a half in length across the vagina, high up in the vagina, close to the cervix, and considerably removed from the arch of the pubes. The finger being introduced discovered a cicatricial band, the sequel of a posterior laceration of the cervix. In consequence of the vaginitis, cellulitis and pelvic peritonitis that occurred a firm union had taken place between the posterior portion of the cervix and the posterior fornix, and by the same process the cervix was drawn high up in the vagina, towards the sacrum, in which the uterosacral ligaments were also implicated. It would have been utterly impossible to make a satisfactory operation had not the constricting, cicatricial band been first divided. On the 28th of December this band was divided, the cervix thoroughly liberated, and several cicatricial bands in the lower portion of the vagina, that had a tendency to constrict the vagina laterally, were divided,

and by that means more space was gained. The amount of bleeding was so great that it obscured the field of operation and prevented the completion of the operation at the time; this was postponed only till the bleeding had entirely ceased, and before the healing process had been instituted to any great extent, or before a cicatrix had formed. Accordingly, three days after the preliminary operation, the operation was continued, the patient being placed on her back. A vulsellum was engaged in the anterior lip of the cervix and the fistulous opening readily brought down near the orifice of the vagina; in this position of the part no trouble whatever was experienced in performing the operation—denuding the margins of the fistula and passing the sutures. Eight or ten silk sutures, antiseptically prepared in a 2 per cent. solution of carbolic acid, were inserted. The patient was then kept upon her back for more than twenty days, with a soft rubber catheter constantly in the bladder, but frequently changed, one catheter not permitted to remain in the bladder more than four hours. Though the patient was an exceedingly nervous, sensitive individual, she yet bore the presence of the catheters very well. About a week after the operation was performed, a slight leakage through the vagina was obtained. The stitches were not removed, however, until the tenth day, when the union was almost complete, so complete that the point through which the water escaped could not be detected; and though assured that contraction would continue and would result in the entire arrest of the escape of water, prudence dictated the continuance of the use of the catheters that the bladder might not be distended and thus retard union. The result was all that could be desired, the woman recovering entirely from the fistula.

The secret of the success of J. Marion Sims, one of the pioneers in this department of surgery, was attributed to the fact that he used silver wire sutures. At that time the agency of sepsis in vitiating operative results was not distinctly recognized; nor was it understood why success seemed to follow the use of silver wire sutures, while failures attended operations in which the silk or any other form of suture was employed. Now it is well established that when silk sutures, antiseptically prepared, are used, the result is just as good or better than after the use of silver wire; with the additional advantage of being more easily manipulated.

The speaker stated he desired to call especial attention to the importance of a thorough division of the cicatricial bands. In the case under consideration it would have been utterly impossible to approximate the margins of the fistulous opening with security without first dividing the cicatricial bands, because the tension induced by the operation would, of necessity, be thereby super-

added to that already existing in the anterior vaginal wall. This omission was unquestionably the reason of the failure of the operation previously performed, which became apparent on the second day thereafter, the sutures having cut through the tissues.

DR. A. H. MEISENBACH said that the non-union in such cases as have been referred to by Dr. Bond may occur from the factors assigned, or it may be due to the fact that the fistula may be in such a situation that it is not readily accessible through the vagina. The speaker said when in Baden he had an opportunity of seeing a patient upon whom Trendelburg had operated for vesico-vaginal fistula. He placed the patient in the position for section of the bladder, the so called Trendelburg position, viz., by elevating the hips very high and letting the head hang down on an inclined plane; by this means the weight of the intestines gravitates from the bladder, and thus very materially enlarges the space by reason of the traction made by the abdominal viscera on the peritoneum. In this position he cuts down on the bladder and has had great success by using this position in operations for stone. Having a patient suffering from vesico-vaginal fistula, who was in such a state that it was impossible to reach it satisfactorily through the vagina, he hit upon this very novel position of opening the bladder, placing the sutures and reuniting the wound on the vesical surfaces, and then having introduced a catheter the operation was complete, and a perfect result obtained, as he saw the patient ten or fourteen days after. Trendelburg tested the bladder for continuity by injecting from four to six ounces of water, and it held the water perfectly. Silk sutures were used and tied in the bladder, the supra-pubic method being adopted.

In operations where very firm apposition of the parts is desired, catgut is not always to be trusted for the reason that great force must be exerted to bring the parts together; and besides on account of its absorbent qualities, one can be sure that he has tied the suture tight enough, and that in a little time the suture may not absorb moisture, and, in consequence of the loosening of the knot, the suture becomes loosened. It is very difficult to handle wire sutures, from the fact that correct apposition of the edges of the wound can not with confidence be obtained with it; the use of a certain amount of force in applying it often produces laceration of the tissue; failures are, therefore, often due, not to the wire, but to the lacerated tissue. It is very hard to determine just exactly how tight to apply the wires.

DR. WILLIAM JOHNSTON: Dr. Bond says that Sims was the pioneer in operations on vesico-vaginal fistulae. Dr. Jobert, of Paris, operated for this affection in 1837; also Sir James Young Simpson later adopted it, and Dr. Bozeman still later operated, but not by the same procedure as Dr. Sims.

DR. BOND: It is a fact, sir, that to Dr. Sims is due the just credit for popularizing the operation for vesico-vaginal fistula. He first operated upon Negro women in the South, and, after achieving numerous successes, he went to New York and there taught the physicians his method of curing vesico-vaginal fistula. He afterwards went to Paris and successfully operated on Empress Eugenie after European surgeons had failed, and thus acquired a world-wide reputation in consequence of his success.

As to the position that Dr. Meisenbach mentions in regard to the operation that he refers to, one insuperable objection to the method of procedure of Trendelburg would be the fact of the impossibility of removal of the sutures, for these, if allowed to remain in the bladder, would constitute nuclei for the aggregation of the salts of the urine, and thus stones would be generated unless the supra-pubic opening was left open until the sutures could with safety be removed. What is the method of getting rid of the sutures?

DR. MEISENBACH: The suggestion of leaving the supra-pubic opening until the sutures could be removed would be a procedure perfectly feasible. Only about ten days are required to secure a firm union if the operation has been successful, and as regards the formation of calculi, even should they generate their removal by modern devices of surgical art is very readily accomplished.

A SPECIMEN.

DR. BLICKHAHN said: The specimen I present for inspection was from a patient of Dr. Pohlman's who was kind enough to furnish me the clinical facts. Dr. Edward Evert, who made the autopsy, has kindly detailed the post-mortem appearances. This heart and its aorta belonged to a man, aged 30, a blacksmith by occupation. He had always been in good health, with the exception of a cough which occurred several years ago, due to bronchitis, the result supposedly of the inhalation of dust and smoke while following his occupation; the cough while it continued was quite severe, but disappeared completely under treatment for the bronchitis. On January 31, the patient worked as usual, and in the evening went to the Union Depot to meet a relative. He drank several glasses of beer, appeared in good health and spirits, and retired 11 P.M. Early Sunday morning, February 1, he awoke suddenly with great pain and dyspnoea. Dr. Pohlman was sent for and on his arrival found the patient cyanosed and suffering from great dyspnoea, cold extremities; no radial or temporal pulse, and only a slight undulation of the carotids. The patient's condition forbade much physical exploration, and no accurate diagnosis of the difficulty was attempted, the attending physician believing death about to ensue and so informed his friends. He,

however, injected ether and whisky subcutaneously, remained with the patient about an hour and then left, expecting, on his return some hours later, to find his patient a corpse. By afternoon, however, the condition of the patient was greatly improved; the pulse was perceptible, the cyanosis less, and respiration less embarrassed, etc. His improvement was steady, and the patient in a short time insisted he was well, and wanted to go to work a day or so later. The doctor insisted he had not satisfactorily diagnosed his malady, the symptoms being still very grave, and he insisted on the patient remaining in bed, etc. The third day the patient got up and walked about the room, feeling, as he said, perfectly well. He awoke in the night, however, of Tuesday or Wednesday, with great dyspnoea and cyanosis. Dr. Pohlman was again summoned, but the patient died before he arrived.

The post-mortem revealed nothing of special import until the pericardium was opened. The heart sac was bluish in color, and when opened it was found filled by large coagula; through this the heart was reached, and lifted out; the heart was replaced and examined from the outside. There was dilatation of the aorta; and inside the sac just after it leaves the heart, there was observed an aneurism and a small irregular opening of the size of a small pin's head, from which the hemorrhage had taken place. The heart otherwise was found in a healthy state.

DR. BOND inquired: Can Dr. Blickhahn give the history of the case as to the possibility of syphilis on his part or that of his parents.

DR. BLICKHAHN replied: From hearsay I learned there was no syphilitic history in the case, though the gentlemen who saw the case earlier, and made the post-mortem, were of the opinion that there might have been syphilis.

DR. BREMER: The question of syphilis is always the one that is uppermost in the mind of an inquirer after truth in such cases. He believed that there is almost no case of diverticulum of the heart, as it was formerly called—or aneurism, which could not be traced to syphilis—not a well authenticated case. In most cases syphilis certainly is the cause, either hereditary or acquired. He had known a case of hereditary syphilis in which the individual died from aneurism of the aorta; that is the only case he had met with in his own practice.

DR. BROOME said that some cases of aneurism are met with, which clearly are not due to syphilis, nor to any known cause. He had now under observation a case in which there is positively no history of syphilis, though the etiology is obscure. The aneurism is from the arch of the aorta and is of enormous size, larger than any heretofore recorded. Subjective symptoms had been manifest for a year and a half; but a palpable tumor appeared only about one year ago. Its

increase in size has been so rapid and great, that pressure on the thoracic walls has occasioned absorption of the entire anterior halves of six ribs, a portion of the sternum and also the sterno-clavicular articulation; the sternal extremity of the clavicle being pushed up against the thyroid cartilage. The patient now complains but little of pain, but previous to the escape of the tumor beyond the contour of the ribs, his suffering was very great in consequence of mechanical pressure of the aneurismal tumor exerted within the thoracic cavity. The doctor endeavored to introduce a silver wire into the sac, but owing to the presence of septa within its cavity, the resistance was greater than could be overcome without exercising undue force. Ordinary piano wire is probably the best, of which from ten to twenty feet might be introduced so large is the sac. Macewen claims to have returned several patients to hard work, apparently completely cured of their aneurismal tumors by his method of treatment. This consists of the introduction and retention of a long needle into the sac just deep enough to strike the opposite wall. The needle is thus practically suspended in the sac, and in consequence of the motion of the blood current being thereby rendered by it tumultuous and disseminated, irritation is set up in the vessel wall, and leucocytes is induced. This process continuing, superimposed accretions of fibrine generated, and a partial thrombosis progresses until complete occlusion of the sac occurs. The method suggested is simple, besides devoid of danger, and appears to be full of promise.

DR. CADWALLADER stated that he had in his possession a specimen taken from a patient who gave a rheumatic history of several years' duration, with a marked disturbance of the heart. He discovered, in making a post-mortem, an aneurism or diverticulum on the superior surface of the left ventricle as large as a walnut. The patient died from some other trouble unconnected with it.

DR. BREMER: No poison circulates in the human body, nor is there any factor that tells to such a degree and with such an intensity upon the vessels, as does syphilis; and next to syphilis comes alcohol. The syphilitic lesion is very frequently confined to the muscular layer of the vessels. The muscular layer is infiltrated and, in consequence, there is a shrinkage of the muscle fibres; there being no resisting power, no elasticity, the blood pressure will have the effect of pushing out and dilating the connective tissue membranes, which have been formed in place of the muscular membrane. In that way miliary aneurisms, when they occur in the brain, prove very frequently fatal. In the same way the larger aneurisms are formed. It is true that traumas are sometimes the cause of aneurisms, traumas which may not be noticed; but the so-called idiopathic aneurisms are probably all due

to syphilitic infection, which, in a great many instances, is a matter unknown to the patients themselves.

DR. BOND: Did I understand you to say that the retrograde metamorphosis incident to syphilis was represented by the conversion of the muscular element into connective tissue?

DR. BREMER: The muscular elements disappear at the site of the lesion, and very frequently in the muscular coat; such is the case in gummata, for instance. The gummata afterwards breaks down to some extent, then connective tissue is formed; and the blood current, the *vis a tergo*, dilates the connective tissue which has been formed. When the connective tissue is in a fresh state—an embryonic state—in a fibro-plastic state—it is very soft, and can be pushed out and a pouch very easily formed.

FOREIGN CORRESPONDENCE.

LETTER FROM LONDON.

(FROM OUR REGULAR CORRESPONDENT.)

Lectures on Nursing—The Electric Light and Human Ailments—The Treatment of Burns—Coöperation and the Nursing Profession—Sir Richard Quain—Diverticulum of the Esophagus—The Midwives' Registration Bill—Miscellaneous Items.

Several of the National Health Society's lecturers are now giving lectures on nursing in the provinces—at Horstead for Lady Berkbeck, at Dedbury for Lady Henry Somerset, and also at Norwich. The lectures are attended by hundreds of ladies. The "homely talks" which follow the set discourses are especially intended for the working women of the districts, and many of the cottage wives and mothers show an earnest desire to be better informed on the important subject of nursing their sick.

The electric light is stated to exercise a most soothing influence over human ailments. According to a medical man, by reflecting the rays of an incandescent lamp upon the sufferer, acute pain is relieved in a few moments. For example, a headache will yield to the treatment in from ten to fifteen seconds, a strong concentration of light on the seat of a malady in any other part of the body will effect a temporary cure in five minutes, and even consumptive patients find their cough quieted and the breathing easier. The light is directed to the affected region through a funnel-shaped apparatus. The treatment is stated to have been tried in Moscow.

In one of the large London hospitals the following method of treatment for burns has been tried with success: The burned surface is first carefully washed with a 2 or 3 per cent. solution of carbolic acid; or with a 3 to 1,000 solution of

salicylic acid. The blisters are then opened and the entire surface covered with subnitrate of bismuth finely powdered, and over this a layer of cotton wool. This dressing is to be renewed as soon as it becomes at all moistened by discharges from the wound. If the burn is very extensive, an ointment of bismuth is substituted for the dry powder. With this dressing cicatrization is found to be much more rapid, and the suffering of the patient much more quickly relieved than is the case with any other form of treatment. It is found that in spite of the large quantities of subnitrate of bismuth which are employed in this manner, up to the present no case of "bismuth poisoning" following its use has occurred.

At once pathetic and pleasing was the spectacle presented at King's College Hospital, on the occasion of the patients' annual Christmas-tree entertainment, the cost of which was borne almost entirely by the students attending the institution. By the judicious use of artistic hangings, Chinese lanterns, evergreens, and flowers, the wards were made to look exceedingly bright and pretty. The patients able to leave their beds were accommodated in the area of the great hall, while those less fortunate were provided with couches in the three surrounding galleries, so that they might share in the enjoyment derivable from an entertainment to which several members of the dramatic profession contributed. Many of the visitors inspected the wards containing patients who had been inoculated with Koch's lymph, which in certain tubercular diseases has been markedly beneficial.

Coöperation is now extended to the nursing profession. Some nurses have combined on a plan which will enable them to receive their own earnings in full, subject to a slight deduction for working expenses. That they are good nurses is guaranteed by the fact that Miss Hicks, the late matron of the Ormond Street Hospital, is their lady Superintendent. It is said that nurses who earn two guineas a week sometimes receive for themselves no more than £20 a year.

Sir Richard Quain, the new medical baronet, is one of the members of the medical profession who is most popular outside his profession. For many years he has been *persona grata* in literary, artistic and official circles, and has numbered among his friends or acquaintances most of the great artists and men of letters of the last two generations. For in spite of his iron-gray hair, active habits and untiring energy in the discharge both of his professional and social obligations, Dr. Richard Quain must have already exceeded the Psalmist's span. At Mallow, Sir Richard first saw the light, and his first introduction to medical practice took place in Limerick. He soon found his way to London and quickly began to make his mark, being for some years the right-hand man of the late Dr. C. J. B. Williams, and

then one of the physicians appointed at the institution of the Hospital for Consumptives at Brompton. For many years now he has possessed one of the leading consulting practices in London. His *magnum opus* is the famous "Dictionary of Medicine," which took some ten or twelve years to prepare, and in the production of which he obtained the assistance of most of the best known medical writers.

At the Pathological Society's meeting, an interesting and rare specimen of diverticulum of the œsophagus, taken from the body of a man aged 49, was shown. The patient, who was much emaciated, and on whom gastrostomy was performed in July, 1890, had given a history of dysphagia extending over a period of ten years. Death occurred two days after the completion of the operation, from pneumonia and exhaustion. The autopsy showed a diverticulum of the back part of the œsophagus 4 inches in depth from the level of the arytenoid cartilages, $3\frac{1}{2}$ inches in breadth and $2\frac{1}{2}$ inches in thickness, with a mouth 1 inch in diameter and a capacity of 6 ozs. The walls of the sac were lined throughout with mucous membrane, and were of the same thickness as those of the œsophagus. When the enlargement was filled with fluid the opening in the œsophagus was firmly closed by the pressure of the distended sac. There was no malignant growth present. The absence of muscular tissue except at the mouth of the sac, supported the contention that posterior diverticula were primarily due to effects of pressure, and not to congenital defect, as held by some authorities.

Dr. G. N. Pitt has published some notes on the post-mortem appearances in chronic alcoholism. *Prima facie*, the chronic dyspepsia and irregular habits of these patients would lead one to expect that their mortality from phthisis would be high. The Registrar General's Reports, however, showed that the mortality from phthisis of publicans and others whose occupations exposed them to special temptations to drink, was rather below than above the average. But acute tuberculosis and pneumonia were very prone to occur in such patients, and the tuberculous nature of the disease might often be overlooked during life. Dr. Pitt concludes that tubercular lesions in the lung in alcoholic subjects generally assume a fibroid form, and that tubercular lesions are not infrequently associated with alcoholic neuritis and hepatic cirrhosis.

The Manchester Medico-Ethical Association, numbering 150 medical men practicing in Lancashire and Cheshire, have taken alarm at the "Midwives' Registration Bill" now before Parliament, and are organizing an opposition to that measure. Sir Walter Foster, M.D., has withdrawn his name from the back of the Bill, and it is stated that others interested in its promotion are persons "having little experience of family

practice." It is also alleged that the General Medical Council has declined to support the Bill, and that the Royal College of Physicians has also repudiated it. In the view of the Association, the measure is a plan for avoiding the extended educational course necessary to qualify any one to treat the diseases of women and children, and that the Bill is to be used as a "back door entrance" for women to the medical profession.

"The Coming Race" is the name appropriated to a bazaar and fancy fête at the Royal Albert Hall, in aid of the West End Hospital and School of Massage and Electricity. The arrangements include a festival dinner to which ladies will be admitted. The fête will be opened on March 4 for four days.

The Swiss Federal diploma which gives the right of practice has been granted to Dr. Holland, of St. Moritz. This act on the part of the Swiss authorities ends a long controversy.

Sir George Humphry, of Cambridge, the new medical knight, has been invited to a congratulatory dinner by the Cambridge Medical Graduates' Club. Among the guests invited is the Vice Chancellor of the University of Cambridge.

G. O. M.

NECROLOGY.

DR. WILLIAM J. McCURE, University of Maryland School of Medicine, Baltimore, (1866), Health officer of York, Pa., and member of the Legislature from Adams County in 1878, died January 24, aged 52 years.

DR. N. M. BEMIS, of Fairbault, Minn., died January 29th, aged 69 years. He was a native of Massachusetts, and graduated at Woodstock, 48 years ago. He moved with his family to Minnesota in 1855 where he has been in active practice up to a few weeks before his death. He was father of Dr. J. G. Bemis of Chicago.

DR. PIERSON RECTOR, President of the Board of Pension Examiners, Jersey City, N. J., died in that city, January 22, of pyæmia, due to a surgical accident while in attendance upon a charity patient. He was born in Duanesburg, N. Y., 52 years ago and was educated in the Racine College and the Albany Medical College. During the war he was Assistant Surgeon 115th Regiment N. Y. Volunteer Infantry, but was transferred with the same rank in February, 1864, to the 127th Reg't Vol. Inf't., of the same State, receiving his discharge December 14, 1864.

MEDICAL DIRECTOR JONATHAN DICKINSON MILLER, U. S. Navy, (retired) died January 29, at his home, Mount Airy, near Philadelphia. He was a native of New York, was commissioned as-

sistant surgeon December 6, 1836, and assigned to the North Carolina, in the Pacific squadron. He was passed in 1841 and assigned to the Naval Hospital, Brooklyn. In 1843 he was ordered to the brig Perry of the East India squadron. He was again promoted in 1847 and ordered to the Gulf of Mexico. He served continuously till November 6, 1872, when he was placed upon the retired list.

DR. CHARLES C. LANCASTER, an alumnus of the Medical College of Virginia, class of 1884, died February 3, at Knoxville, Tenn. He was poisoned by a gangrenous wound, which he had surgically treated, through an abrasion under his finger nail.

DR. ALVIN TALCOTT, the most distinguished although not quite the oldest surviving citizen of Guilford, Conn., died there Jan. 17. He was born in Vernon, Conn., Aug. 17, 1804. He was graduated at Yale in 1824, and from the Yale Medical School in 1831. He began to practice in Vernon as successor to Dr. Dow. Dr. Talcott had taught in Guilford during his college course, and there married Miss Olive Chittenden, on March 7, 1831. He settled in Guilford about 1840, and became a successful practitioner. He began early to search out the genealogy of the Guilford families. He wrote out in manuscript the full family lists, as far as obtainable, of all Guilford's forty original settlers of 250 years ago. This notable genealogical work is embodied in an imperial quarto containing over 25,000 individual names. It is understood that it is bequeathed to the New Haven Historical Society. Dr. Talcott was many years secretary and treasurer of the Board of Trustees of Guilford Institute, himself an active and ready classical scholar. For some years he held the office of Town Register. He had three children—one son and two daughters—who died at an early age, Mrs. Talcott having passed away December 8, 1882.

DR. NATHANIEL R. BOUTELLE, Jefferson Medical College, 1847, died at his home in Waterville, Me., December 21, of paralysis. Besides being an active practitioner, he was a bank president, and an enthusiastic stock breeder.

BOOK REVIEWS.

A TEXT-BOOK OF COMPARATIVE PHYSIOLOGY FOR STUDENTS AND PRACTITIONERS OF COMPARATIVE (veterinary) MEDICINE. By WESLEY MIMMS, M.D., D.V.S., etc., Professor of Physiology McGill University. With 476 Illustrations. New York: Appleton & Company, 1890. Pp. 636. \$3.00.

This compact and thoroughly well arranged

volume will be a desirable addition to any library. Though written for veterinarians it is based of necessity on human physiology, and the recent contributions to this department of knowledge are clearly set forth. The author's style is terse and entertaining, carrying one along agreeably over what otherwise would be dry, statistical and unentertaining. The illustrations, though rarely original, are well selected, and graphic demonstrative methods are emphasized.

THE EXTRA PHARMACOPOEIA.—With the additions introduced into the British Pharmacopoeia, 1885. By WILLIAM MARTINDALE, F.S.C., late Examiner of the Pharmaceutical Society and late Teacher of Pharmacy and Demonstrator of Materia Medica at University College. Medical References and a Therapeutic Index of Diseases and Symptoms. By W. WYNN WESCOTT, M.B. Lond., Deputy Coroner for Central Middlesex. Sixth Edition. London: H. K. Lewis, 136 Gower st., W. C. 1890.

This concise little volume is familiar to American as well as to English physicians, the present edition numbering the thirty-sixth thousand copies.

The necessary revisions have been made. The derivatives obtained from coal, tar and alcohol, which are now so prominently presented as new remedies, are incorporated in the text. The volume is compact in form, with flexible morocco cover, and can be conveniently carried in the pocket. The posological tables are very complete, and the Therapeutical Index at the close of the volume will be found helpful, as suggestive of appropriate remedies, especially in times of emergency.

A TEXT-BOOK OF PRACTICAL THERAPEUTICS: WITH ESPECIAL REFERENCE TO THE APPLICATION OF REMEDIAL MEASURES TO DISEASES, AND THEIR EMPLOYMENT UPON A RATIONAL BASIS. By HOBART EMORY HARE, M.D., (Univ. Pa.), B. S. C., Clinical Professor of Diseases of Children and Demonstrator of Therapeutics in the University of Pennsylvania, etc.

This valuable and practical work of over six hundred pages is published by Lea Brothers & Co., in their usual creditable style. The aim of the author has been in a very effectual way to bridge the chasm which lies between the theory and the practice of medicine. To this end the physiological actions of remedies are clearly set forth so far as they are known, and the pathological condition in which their use is indicated, are concisely described. The reason why in particular stages of diseases particular remedies are required is just that which the young physician most needs to know, and the ready reference to the drug that shall meet that requirement, and the reason for its use, is just the instruction which

raise one from empiricism to the higher plane of rational practice.

We can heartily commend the work for its intelligent and reliable review of the prominent therapeutical agents in use, and for its intelligent explanation of the reasons for their administrations in the treatment of diseases. The remedies considered are arranged in alphabetical order, as are also the diseases to which reference is made. A valuable portion of the work is that devoted to remedial measures other than drugs and to the consideration of goods suitable for the sick. A table of doses of remedies and a copious index add to its value and convenience. An examination of the work will ensure approval, and as a practical reference book it will be found helpful.

ASSOCIATION NEWS.

American Medical Association.

Forty-Second Annual Meeting, at Washington, May 5 to 8, 1891.

LOCAL COMMITTEE OF ARRANGEMENTS.

D. C. Patterson, M.D., *Chairman*; C. H. A. Kleinschmidt, M.D., *Secretary*.

SUB-COMMITTEES.

Registration.—Drs. Bulkley, J. O. Adams, Bovee, Herman H. Cook, Eliot, J. D. Morgan, Manning, J. D. McKim, Mallan, Osmon, Ober, Radcliffe.

Finance.—Drs. Stanton, B. B. Adams, Balloch, Crook, Chamberlin, Harrison, Hood, Magruder, Newman, Sowers, Toner.

Entertainment.—Drs. Prentiss, Bromwell, Deale, Fenwick, Franzoni, Hyatt, Johnston, H. L. E. Johnson, Richardson, Rixey (U. S. N.), Witmer.

Transportation.—Drs. Hawkes, Acker, Burnett, Lee, Mundell, Townsend, Jas. T. Young.

Hotels and Boarding Houses.—Drs. Reyburn, Brackett, Friedrich, Leach, Lamb, Murphy, Sothern.

Reception.—Drs. Lincoln, Bryan, Fry, A. Hegar, U. S. A., J. T. Johnson, Loring, Mackall, Marrison, Peter, A. C. Patterson, Rosse, T. R. Stone, T. C. Smith, Walsh.

Place of Meeting of Sections.—Drs. Lovejoy, Beatty, Bayne, Callan, Hill, D. H. Hazen, H. Leach, McLaughlin, J. C. McGuire, Neale, Spriggs, J. T. Winter.

Information.—Drs. Hickling, B. B. Adams, S. W. Bogan, Byrns, Neale.

Exhibits.—Drs. Patterson, S. A. H. McKim, Stanton, Toner.

Printing.—Drs. Hamilton, Barker, Briscoe, W. P. C. Hazen, Henderson, Poole.

The several Committees, as well as the Committees as a whole, have met and mapped out the

work in hand for the accommodation of the Association. The General Meetings will be held in the auditorium of Albaugh's Opera House, the basement of which having been secured for the exhibits.

SPECIAL CORRESPONDENCE.

The Effects of Anæsthetics Modified by Altitudes.

To the Editor:—The case which I desire to report caused much unfavorable comment in the community where it occurred, namely, one of the high mountain cities of Colorado—elevation 10,000 feet. Surgeons use chloroform at these extreme elevations almost exclusively. For some occult reason either, or any of the anæsthetic mixtures do not act well, and are considered by common professional consent dangerous; not because they have frequently produced death, but because of the enormous quantity necessary to produce anæsthesia. For this reason chloroform, which causes complete insensibility very speedily, and in small quantity, is mostly used.

On January 18 of the present year a man of 37 years of age was placed under the influence of chloroform for operation for organic urethral stricture in the spongy urethra. The stricture was of small calibre and the individual had had several attacks of retention following debauches. In the course of the chloroform the subject presented no symptoms of an alarming character until efforts were made to operate by the cutting method when, suddenly, the respirations stopped, a few convulsive shudders, a few flutters of the heart, and the patient was dead. Artificial respiration, ammonia by hypodermic injection, and the interrupted current failed to give the slightest encouragement, as a means of resuscitation.

These matters came to my knowledge as coroner's medical adviser, popular indignation demanding investigation and prosecution criminally of the unfortunate medical attendant. The post-mortem examination revealed heart dilatation, enlarged spleen, liver—results of chronic alcoholism. As chloroform is given in this locality many times each month, and as this is the first recorded death in ten years from chloroform, it has attracted more than ordinary public attention.

Dislocation of Long Bones.

To the Editor:—In No. 6, Vol. 16 of THE JOURNAL I find a communication from Dr. Murdock to the Allegheny County Medical Society giving the details of the reduction of the dislocation of the head of the right femur upon the dorsum of the ilium by extension and counter extension; which brings forcibly to my mind two principles laid down by two eminent men in regard to dislocations of long bones. One by the late lamented Prof. Moses Gunn, of Rush Medical College, Chicago, to-wit, always make extension in the line of deformity. The other, by the late lamented and eminent George Sutton, M.D., of Aurora, Ind., which is: In reduction of the head of the femur or humerus, use a fulcrum in the groin or axilla by which the long arm of the lever, the femur or humerus, as the case may be, can be used efficiently. In the case cited by Dr. Murdock both of these principles were brought to bear. The foot of the young medical student in the groin was the fulcrum and extension was made in the line of deformity. When the thigh of the dislocated limb was brought across the thigh of the sound one the pressure necessary

to effect this was sufficient, acting on the long arm of the lever, the femur pressing on the fulcrum, the student's foot, to raise the head of the femur over the lip of the acetabulum, and all extension then had to do was to cause the head of the femur to travel back through the rupture of the capsular ligament and drop into its place in the acetabulum. The position the dislocated limb was made to take also relaxed the V ligament.

This case also is a confirmation of the position taken by Dr. McCann in the discussion, contrary to the position of Dr. Murdock, that dislocation does not take place at any other point than at the lower and anterior portion of the acetabulum. In the case cited if the capsular ligament had not been ruptured externally and upwardly the means used for reduction would not have been successful, but if it had been torn inferiorly and anteriorly it would have been reduced by manipulation if a fulcrum had been used in the groin.

JAMES LAMB, M.D.

Aurora, Ind., Feb. 17, 1891.

Absence of Uterus.

To the Editor:—The interesting case reported in No. 8 of THE JOURNAL by Dr. McShane, of Carmel, Ind., recalls to mind a case I had a few years since. A lady, aged 24 years, consulted me to ascertain why she could not have children. She had been married six years, was well developed, not masculine; breasts were normal, the puerium normal, and well covered with hair.

I found by digital examination a good-sized vagina, but no cervix uteri; in fact, there was nothing but a smooth, well arched vagina, about 4 inches in depth. I introduced a sound into the bladder, and with my finger in the rectum I could readily feel the sound, showing that there was complete absence of the uterus.

Having been a member of the Association for several years, I think it best to let well enough alone and publish THE JOURNAL at Chicago.

H. W. CARPENTER, M.D.

Oneida, N. Y.

A "Practical Note."

To the Editor:—I am very glad to see your "Practical Notes." Keep it up and enlarge, and as you have one for carbuncle I will try to help you out with mine. In 1855 Stone and Hunt, of New Orleans, taught the incision. I kept it up under cocaine. Now then fill the carbuncle full of dry salicylic acid, it completely dissolves all the hard white tissue; wash it away with sublimate soap and hot water; fill cavity with peroxide of hydrogen, when bubbling ceases sponge out with cotton; dress with basilican ointment and as soon as matter reforms repeat acid, etc. It makes a rapid and painless cure.

A. P. BROWN, M.D.

Fort Worth, Tex., Feb. 19, 1891.

Shall The Journal be Removed to Washington?

THE ACTION OF THE CHICAGO GYNECOLOGICAL SOCIETY.

The following resolutions, formulated by a committee appointed at a preceding meeting, were adopted by the Chicago Gynecological Society February 20, 1891:

WHEREAS, There is a disposition on the part of a portion of the Board of Trustees of THE JOURNAL of the AMERICAN MEDICAL ASSOCIATION to move THE JOURNAL from its present place of publication, Chicago, to Washington, D. C., and

WHEREAS, The Board of Trustees invites a free discussion in the columns of THE JOURNAL, with a free expression of opinion from societies and individuals be it therefore

Resolved, That it is the opinion of the Chicago Gynecological Society, that any change in the place of publication of THE JOURNAL, at this time, will be detrimental to the interests of THE JOURNAL as well as to those of the Association, and be it further

Resolved, That the delegates elected from this Society to the

next meeting of the Association be duly instructed to oppose in every legitimate manner such removal.

(Signed)

HAYWARD HOLMES,
HENRY T. BYLORD,
HENRY P. NEWMAN,
FRANKLIN H. MARTIN,
Committee.

To the Editor:—I have watched with considerable interest the lengthy and numerous discussions which have been presented in your columns in regard to the proposed removal of THE JOURNAL to Washington. I cannot see wherein any advantage whatever would accrue to THE JOURNAL by such a change in its location. The American Medical Association is not a sectional body; or if it is open to the charge of sectionalism at all, as some may maintain, it certainly is not an Eastern organization. The greatest loyalty to its integrity, honor and development, cannot be claimed by the medical profession of the States East of the Alleghany mountains, as a body. This remark is not intended to reflect in the least upon the illustrious services of a large number of Eastern physicians without whose cooperation the American Medical Association would not be what it is to-day. Nevertheless the fact as stated cannot be successfully challenged.

THE JOURNAL was born and has been reared in the West. And while it may not have become all that its promoters could wish it to be, yet the assumption that it could have done better, or even as well, any place else is entirely gratuitous. Unlike the Association THE JOURNAL must have a habitat; and, irrespective of any other consideration, it should be located somewhere near the geographical centre of the distribution of the membership of the Association. This might be a reason for moving it farther West than Chicago if such another centre could be found in that direction, but certainly is an objection to its removal Eastward. It would make a difference of at least one day in its delivery to all points West of Chicago by removing it to Washington. So much for the geographical question.

In regard to the facilities for journalistic enterprise, Washington is not ahead of Chicago in any single point except the National Library. The Chicago profession is easily the peer of that of Washington. The business interests represented by Washington are scarcely worth mentioning in comparison with those of Chicago. So that whatever advantage might be derived from local business interests by the advertising department, which is certainly an important feature in the medical journal of to-day, would all be in favor of Chicago.

Those who are inclined to criticize the status of THE JOURNAL, and the grade of its contributions should remember that as an organ of an Association meeting once a year it is placed at an enormous disadvantage. Papers written and read at the annual meeting are scattered through the fifty-two weekly issues of THE JOURNAL, half of them being more than six months and many of them nearly one year old before they appear. In this age of enormously rapid progress many papers and facts grow stale or obsolete in much less time than that. Besides this it is impracticable for the officers of Sections to exercise any discriminating judgment in regard to what shall be placed upon the program. And while the general standard may be, and I believe is creditable, and in many instances ranking very high indeed, there must necessarily be an unfortunately large proportion of rubbish mixed with it. These are difficulties not peculiar to Chicago, but simply peculiar to this method of conducting a journal in the interests of an organization which meets only once a year. It seems to me that we should set ourselves to work in some way to remedy the defects of THE JOURNAL inherent not in its location or editorial management, both of which are creditable to a high degree, but rather dependent upon the peculiar circumstances under which it is published.

G. W. McCASKEY, M.D.

26 W. Wayne St., Fort Wayne, Ind., Feb. 16, 1891.

To the Editor:—As a member of the Association, I have carefully read and compared the various reasons assigned for the removal of THE JOURNAL, or for continuing its publication in Chicago, wishing, in casting my vote, to do so only after mature consideration.

It would occupy too great space to review the pros and cons—the arguments offered on both sides of the question—those of Dr. Solis-Cohen's removal article, so ably replied to by Harold N. Moyer, M.D., and Harvey Reed, M.D.; the spicy and patriotic non-removal vote of E. Cheney, M.D.; besides various other articles appearing in THE JOURNAL under the heading: "Shall THE JOURNAL be Removed to Washington?"

Permit me, on so appropriate an occasion, to offer the tribute of my sincere esteem to Dr. E. Cheney, for the display of such unbiased and patriotic sentiments as expressed in his letter to THE JOURNAL of January 27. Certainly, if Pope was a contemporary with Dr. Cheney, he would have found an exception to the doubt expressed in the lines:

"Where is the man who counsel can bestow,
Unbiased or by favor or by spite."

Please record my vote *against* removing THE JOURNAL from Chicago, and *especially* against removal to Washington.

"Come, your reason, Jack, your reason."

While my reasons may not be "as plenty as blackberries," there being no compulsion, as in Sir John's case, I will simply urge the objection to Washington, on strictly sanitary and hygienic reasons.

I respectfully call the attention of the Trustees of the Association to page 867, "Da Costa's Medical Diagnosis," seventh (last) edition, line 17 to line 39.

Under article "Fever," calling attention to the effects of malaria in simulating acute meningitis, Prof. Da Costa states that the patient had spent part of his summer vacation in the *marshy* neighborhood of Washington—the cerebral symptoms arising in which case so simulated acute meningitis, that it was only through the use of the quinine treatment that a differential diagnosis could be arrived at.

In this connection, one of the most prominent scientific members of the medical profession in the United States, in an address before the British Medical Association, not many years ago, in speaking of the deleterious effects of malaria upon the human system, declared that malaria was antagonistic to high mental culture, or words to that effect.

I think that for the successful publication of THE JOURNAL, it should be kept as far as possible from all marshy or malarial centres, that the intellectual faculties of the editor, publisher and typesetters, *et hoc genus omne*, connected with it, may enjoy the full scope to be attained only in a pure atmosphere, uncontaminated by antagonistic intellectual influences. "*Stare decisis, et non quicquid moerere*," is a law maxim it would be well to bear in mind, in considering the question of the *locus in quo* for THE JOURNAL.

C. D. OWENS, M.D.

Pres. Louisiana State Medical Society.
Eola, La., February 16, 1891.

To the Editor:—As a member of the American Medical Association I wish to record my name "with the crowd" and say: Let the place of publication remain where it is. I think, with Dr. John M. Batten, that it should remain in its *native habitat*.

H. C. FAIRBANK, M.D.
Flint, Mich., Feb. 20, 1891.

To the Editor:—If the home of THE JOURNAL must be removed from Chicago, let it come to Galena, Ill. It was the home of Grant, Washburn, Rawlins and other great men. It is far more central than Washington and has eight physicians, equally inexperienced in editorial work with their brethren of the Capital City, and equally full of enthusiasm for the good work.

We of Galena are far from the maddening and demoralizing influence of political parties and their intrigues, and when we come home from our muddy country rides and hang up our splashed overcoats, we can give to our editorial work the full power of our massive intellects.

I think Chicago the proper place for the home of THE JOURNAL, but as I said before, if it must be removed let it come to the central city of Galena, and not to the outer edge of the territory at Washington.

HENRY T. GODFREY, M.D.

Galena, Ill.

To the Editor:—If THE JOURNAL should be moved to Washington City I am fearful much of its life and vigor would be lost. Business activity is contagious, and in Chicago we have the benefit of the stimulus of this kind of an epidemic all the time.

J. T. MC SHANE, M.D.

Carmel, Ind., Feb. 23, 1891.

To the Editor:—Keep THE JOURNAL in the great city of the enterprising West. Chicago is the only city that presents so many advantages for the publication of THE JOURNAL.

J. J. GARVER, M.D.

Indianapolis, Ind., Feb. 23, 1891.

To the Editor:—Permit me, as a member of the American Medical Association since 1877, to interpose my decided opposition to the removal of THE JOURNAL to Washington or anywhere East. From my standpoint I cannot see any good reasons for the change, while to the contrary, many sufficient reasons have already been suggested, by many members from different points of the compass, why it *should not* be removed to Washington, but should remain in the great central interior city of Chicago, where it first saw the light, and where it has served us so well.

J. H. DAVISSON, M.D.

Los Angeles, Cal., Feb. 19, 1891.

To the Editor:—To some men the arguments in favor of Chicago are too obvious and too numerous to require enunciation. Insane or insincere men I have neither time nor inclination to labor with. Yours for Chicago, ten thousand times Chicago!

DONALD MACLEAN, M.D.

Detroit, Mich., Feb. 23, 1891.

MISCELLANY.

Official List of Changes in the Stations and Duties of Officers Serving in the Medical Department, U. S. Army, from February 14, 1891, to February 20, 1891.

Lieut. Col. Charles C. Byrne, Surgeon, is relieved from duty at Ft. Sam Houston, Tex., and will report in person to the commanding General, Dept. of the Columbia, for duty as Medical Director of that Dept., relieving Col. Bernard J. D. Irwin, Surgeon. Col. Irwin, on being relieved by Lieut. Col. Byrne, will proceed, via San Francisco, Cal., to St. Louis, Mo., and report in person to the commanding General, Dept. of the Missouri, for duty as Medical Director of that Dept., relieving Col. Charles Page, Asst. Surgeon General. Col. Page, on being relieved by Col. Irwin, will report in person to the commanding General, Div. of the Atlantic, for duty as Medical Director of that Division. By direction of the Secretary of War. Par. 6, S. O. 36, A. G. O., Washington, February 13, 1891.

Capt. Louis M. Maus, Asst. Surgeon, is relieved from duty at Ft. Stanton, N. M., and will report in person to the commanding officer, Whipple Bks., Ariz., for duty at that station, relieving Capt. Richard W. Johnson, Asst. Surgeon. Capt. Johnson, on being relieved by Capt. Maus, will report in person to the commanding officer, San Carlos, Ariz., Ter., for duty at that station. By direction of the Secretary of War. Par. 7, S. O. 35, A. G. O., Washington, February 1, 1891.

CORRIGENDUM.

In THE JOURNAL of February 21, page 286, next to the last line in third paragraph, for "bladder" read "blades."

ADDRESSES.

FORCED RESPIRATION.

An Address delivered before the Buffalo Medical and Surgical Association, January 1, 1891.

BY GEO. E. FELL, M.D., F.R.M.S.,

OF BUFFALO, N. Y.

LATE PRESIDENT OF THE AMERICAN SOCIETY OF MICROSCOPISTS,
PROFESSOR OF PHYSIOLOGY AND MICROSCOPY MED.
DEPT. NIAGARA UNIVERSITY, ETC.

It may be well to premise what I have to say by calling attention to the difference in the meaning of the terms used. We understand by *artificial respiration*, an artificial method of breathing for an individual; but since forced respiration has been used, with such remarkable results, it seems to me terms should be employed which would be distinctive, and some time ago I made a suggestion to the profession which seems to have been quite universally adopted, to the following effect:

Auto-respiration: respiration by the individual for himself.

Deep Respiration: forcible respiration by the individual himself.

Artificial Respiration: this we understand to be that produced by the methods which have been suggested by Sylvester, Howard, Marshall Hall and others, in which movements of the limbs of the patient and pressure are made so as to draw the air into the lungs. In many instances artificial respiration cannot be depended on to furnish a sufficient supply of air to the lungs.

Forced Respiration: those measures by which air is forcibly passed into the lungs. (I do not advocate forcibly withdrawing it, because I think it to be an unphysiological method.)

At the late Berlin Congress Professor Horatio C. Wood, of the University of Pennsylvania, the only American, I understand, who delivered an address before the Congress, spoke about John Hunter and others having devised an apparatus for the purpose of breathing for an individual where it was necessary to do so. I will quote from Professor Wood's address on "Anæsthesia" his remarks in this connection, which will indicate that some of the brightest lights of medicine have considered the subject of forced respiration, but have not demonstrated its value;

but, through the failure of their efforts, rather relegated it to the field of impracticable methods.

The use of what may be called "forced" respiration by the physiologist so naturally suggested a similar practice in man, that the celebrated John Hunter invented for the purpose an apparatus which consisted of a bellows so constructed that when it was extended one compartment drew in air from the lungs, whilst the other drew air from the atmosphere; and when it was closed the process was reversed, the fresh air being thrown into the lungs, the foul air into the atmosphere. In 1857, Richardson, of London, invented an apparatus more elegant and portable, although identical in principle with that of John Hunter's; but I have not found that either Hunter or Richardson treated by forced artificial respiration an actual case of disease or poisoning. In 1875, *Boston Medical Journal*, Vol. xxi., Dr. John Ellis Blake reported a successful case of aceton poisoning, in which life was apparently saved, although there was no pulse for over three hours, by artificial respiration, with the use of oxygen. In this case Marshall Hall's method was at first used, but later a small rubber tube was connected directly with a copper reservoir of condensed oxygen, the other end of the tube terminating in a small nozzle, which was inserted in one nostril. Four hundred gallons of oxygen were thus used, but how far the force of the compressed gas was employed to dilate the lungs is not very clear; and it is somewhat doubtful whether this case should be considered as one of forced respiration. The first physician to use forced respiration in actual human poisoning, with a clear idea of its value and power, so far as my reading goes, was Dr. George E. Fell International Medical Congress, Washington, 1877.

It is plain that the bellows constructed by John Hunter and by Richardson are unnecessarily complex and faulty in principle. There is no need whatever of drawing the air out of the fully filled lungs. Every physiologist knows that when the muscular system is completely paralyzed by morar or even by death, that the chest-walls have sufficient elasticity to force air out of the lungs, and all ordinary laboratory apparatus for artificial respiration is based upon this fact. For forced artificial respiration in man, an ordinary bellows of proper size is all that is required for the motive power.

The real difficulty—the point to be especially investigated and studied—is as to the connection between the bellows and the lungs. Hunter and Richardson simply placed a tube in one nostril, closing firmly the other nostril and the mouth of the subject.

Dr. Fell at first used a tracheal tube, the insertion of which, of course necessitated the performance of tracheotomy. In one case, however, a simple mask covering the mouth and nostrils was a perfect success. I have had no opportunity of trying the apparatus on the living, but have made a series of experiments upon dead bodies, which have demonstrated that usually a face-mask is all that is necessary for the performance of artificial respiration. Before using the mask the tongue should be well drawn forward, and if necessary fixed in this position by

an ordinary piece of suture silk run through it, which can be held in the hand of the operator. If in any individual case the mask fails, an intubation tube may be introduced into the larynx. I do not believe that it is ever necessary to perform a tracheotomy.

Dr. Fell's apparatus consists of a pair of foot-bellows (the bellows have always been used by hand power), by which air is forced into a receiving chamber, which is connected with an apparatus for warming the air, and a valve which can be opened and shut by a movement of the finger. This valve in turn leads to the tracheal tube. When the valve is opened the air rushes through the chamber into the lungs and expands them; the finger is lifted, the valve shuts, the lungs contract; and so the respiration goes on. I have no doubt that this apparatus is efficient in practice, but it is open to the serious objection of being unnecessarily complex and costly.

A much simpler, cheaper and probably equally efficient apparatus may consist simply of a pair of bellows of proper size, a few feet of India rubber tubing, a face-mask, and two sizes of intubation tubes. There should also be set in the tubing a double metal tube, with openings so placed that their size can be so regulated by turning the outer tube (similar to that commonly found in the tracheal canula of the physiological laboratory), so that it is in the power of the operator to allow for the escape of any excess of air thrown by the bellows. I suppose this whole apparatus could be prepared at a very small cost, and it seems hardly necessary to point out its probable value in various narcotic poisonings, and in other accidents in which death is produced by a temporary paralysis of the respiratory centres. The proper use of it could be taught to persons without special medical skill, so that it ought to form a part of not only the surgeon's outfit, but might be of great service in life-saving stations, about gas-works, etc.

I will comment on Prof. Wood's article later on.

My first operation of forced respiration, was not made upon the spur of the moment. I had thoroughly considered it, for fully a year, but when the opportunity did present it was a remarkable one, and I took advantage of it. Shortly after that first operation I made a series of notes upon what I believed to be the value of the operation. These were made in my note-book in the year 1887. I then said that I believed forced respiration would accomplish more than any method of artificial respiration, either in cases of drowning, or even in cases of shock—in cases of asphyxia of whatever nature. I am glad to state now that I am more than ever satisfied of the truth of those statements. In the last case which I will report here to-night, the demonstration will bear this out.

I should like to enter somewhat into the interesting experiences which I have had since making my first operation, and the trials and tribulations to which I have been subjected in the promotion of the measure; but I presume that any one who makes an operation possessing so far reaching an import as does forced respiration, will probably have a like experience. I made my first operation in July, 1887, and saved a life which I had thought there was no possibility of saving. When I made tracheotomy in that case I felt that I was making the operation

upon a cadaver, and worked accordingly. When the man gave evidence of life, I was as much surprised as any one present. I rightfully became quite enthusiastic over the operation. When some time afterward, I went to Pittsburgh as Treasurer and Custodian of the American Society of Microscopists, to attend the annual meeting of that Society, it was suggested that I might explain my methods to some of the physicians there. Some of Pittsburgh's ultra-conservative physicians, however, thought it was just as well to let me go to Washington, where I was intending to read a paper on the subject, "for fear there might be some under-hand business about it." Then, some of our Buffalo physicians intimated that what I had done was nothing novel; the operation was an old one, said they; dogs had been treated (*killed*) by forced respiration ever since vivisection came to be utilized in the medical colleges. I was well aware of that, but I had never been taught in medical college that forced respiration would save even a dog's life, much less the life of a human being. And this was the teaching of the world at that time. I knew that my apparatus was original in its conception, practicability and results, and took steps which assured this fact. As a further fact, to show what even at the present time the teaching is, and to indicate the necessity of repeatedly presenting this subject to the profession, I will merely state, that if you will turn to the last "Blakiston's" "Visiting List," you will find, under "Marshall Hall's ready method in asphyxia," that the directions are to "avoid the immediate removal of the patient, as it involves a dangerous loss of time; *also the use of bellows or any forcing instrument.*" This is what the medical profession was taught to believe at the time I made my first operation. I was treading upon the accepted principles of the profession, and liable to severe censure had I failed in my first operation.

Well, as stated, I went to Pittsburgh, and the conservatism of the profession showed itself there by refusing to listen to what I had to say upon the subject. When later, I went to Washington, I was not heralded by any fore-runners, was acquainted with but very few individuals at the International Congress, and it was with the greatest difficulty that I had an opportunity to read my paper at all; and what was the most peculiar feature of the whole circumstance was, that, even among a class of men supposed to possess the highest medical knowledge, not any of them saw the point which presented in that first case of forced respiration, in which I breathed for a man two and one-half hours with a tube in his neck. They did not grasp that point. And I now make the statement, without fear of contradiction, that there was not a paper presented at the International Congress at Washington which had a

¹ I do not agree with Dr. Wood, reasons given further on. F.

farther reaching import, if to save human life is desirable, than that little paper on "Opium Poisoning," which I presented—a paper embodying in it demonstrations which would alter and advance one of the greatest medical practices of the day, a practice of wide application. It demonstrated what was before not practically accepted in medicine, that we could force air into the lungs for an almost unlimited period without danger to the delicate lung tissue. Dr. Vandenburg, of Columbus, Ohio, a disinterested observer, speaks of it as "one of the most interesting and valuable therapeutic discoveries of the day."

When I managed, however, to read my paper at Washington, they did me the kindness (?) not to publish it in the proceedings. After I had saved my third life, however, by forced respiration, and the world could not question methods which were so positive in their demonstrations, and so undeniably original, there not being a similar case on record, I had a discussion with the Chairman of a Section, and also with the Secretary-General of the International Congress, and from that discussion, which can be produced if it should be necessary, it was evident that my paper either was not carefully read, or the principal point conveyed by it was not grasped by the members of the committee.

In my first case, a man had taken 20 grains of morphia. After two and a half hours of forced respiration with the apparatus his life was saved. That is, after the dilatation of asphyxia had taken place, and all known methods had failed.

In the second case (not mine), a man had taken 8.24 grains of morphia. This case occurred in Vienna, Austria, two months after my first case. After four and a half hours of forced respiration, that is, you must note, after artificial respiration had failed to do any good, the patient was saved by forced respiration.

In the third case (my own), a man had taken 2 ounces of laudanum. It had been demonstrated that artificial respiration would not save him. He was dying. Then we began with forced respiration, and after fourteen and one-half hours with the new apparatus which I had devised, his life was saved. That was by tracheotomy.

But the fourth case came. A man had taken 2 ounces of laudanum, had severed the anterior jugular vein, and had lost a large amount of blood. For twenty-one and one-half hours continuously applied forced respiration kept him alive until he could breathe for himself, and then in a few hours he asked that it be applied again. He is now living in the southern part of the States, in good health. In this case was demonstrated a very interesting point which has not been brought out prominently, which is, that in a case of great loss of blood from hæmorrhage it does very little good to inject ether or brandy

into the peripheral capillaries, unless you can inject it into, or proximally to a large vein, where you know it will be taken into the circulation. The patient laid in bed nearly two months merely because the ether and brandy which had been injected into the chest produced a gangrenous condition of the tissue. The fluid was not carried off by the capillary circulation, and the muscles of the chest sloughed away, down to the ribs. In the thigh, where injections had also been made, owing to the same cause existing, a weak or very slow capillary circulation, an abscess formed, and a cup of pus was removed on the first incision. This demonstrated very interestingly the necessity of care in the employment of hypodermic medication where there is excessive hæmorrhage.

Following these interesting cases, came a series in which the results were not so successful. An old gentleman, 80 years of age, had taken 1 ounce of laudanum. At the hospital artificial respiration was used, the hospital physicians gave him up. Then forced respiration kept him alive for some twelve hours after that.

One of my most interesting cases was a little child, 18 days of age, of one of our prominent citizens, which had accidentally been given 1 grain of morphia by a physician of the homeopathic school. The little one took the whole of the poison, equivalent to about eighty doses, and came under the influence of it. It was given about a quarter to one. I was called at five o'clock. Without proper apparatus I went to work and made tracheotomy, a most difficult undertaking in one so young; but I succeeded in getting down to the trachea. I then with a small catheter inserted into the trachea, kept up forced respiration, with bellows and valve, with the result that the little one, which was markedly cyanosed, became of a natural hue, the blood became oxygenized, and it breathed for itself a short time. The bowels moved and the evidence was strong that the child might live. But owing to the long time during which the asphyxiated condition had lasted through the influence of the poison, it was too much to expect that we could retain the vital condition of the tissue of the brain for a sufficient time, as was demonstrated by the heart failing to act some four hours after the forced respiration was begun, when death supervened. This was one of the most striking demonstrations I ever had of the value of forced respiration.

Again, it is usually conceded that when you can obtain no pulse at the wrist and no heart action on auscultation, that an individual is (nearly) dead. This condition existed in one instance which occurred. It was a case of opium poisoning. The day before this case presented, I was about to make tracheotomy and carry out my operation in another case, when I noticed indications that the patient would probably live with-

out it; we waited, and he did pull through without the operation. The next day I had the case referred to. I waited until there was no pulsation at the wrist, and could detect no heart action on listening over the chest-wall. I then made tracheotomy. The blood was markedly venous, but upon passing oxygen into the lungs it became oxygenized and red, and furthermore, the heart action became distinct, and the pulse again was present at both wrists. But after an hour the heart again ceased beating. I had waited a little too long before beginning the forced respiration.

After this I demonstrated another method, by which we could perform forced respiration without tracheotomy, and the first application of it occurred in trying to keep alive a still-born infant by passing a tube into the mouth and compressing the nostrils; I succeeded in keeping it alive for a number of hours. Owing, however, to compression of the brain produced in labor which existed, there was evidently no chance for the child to live, and I gave up the attempt. So long, however, as the forced respiration was kept up, the heart continued to beat.

Then came another case which demonstrated, also, that life can be kept up by forced respiration without tracheotomy. A man had taken 2 ounces of laudanum. One of the physicians² present called attention to the dilatation of the pupils as an indication of the very near approach of death. I had begun to make the operation for tracheotomy, but found the blood markedly venous. I stopped, and inserted the tube of the apparatus in the mouth, closed the nostrils and forced air into the lungs through the mouth, and had the satisfaction of seeing the blood in the neck turn from a dark purple to bright scarlet, indicating that there was sufficient heart action to carry the oxygenized blood through the system, and demonstrating the valuable fact that through the mouth and the nostrils sufficient air could be made to pass to the lungs for a time to retain life without the necessity of tracheotomy. This subject seemed to have a mania for committing suicide by taking laudanum, and afterward took 2 ounces of laudanum and about 5 or 6 grains of morphia; I repeated the operation of tracheotomy, and again saved him. Upon making a third attempt he was sent to the asylum, and is now, I believe, cured of his peculiar habit.

Another case presented in which a young woman took 2 ounces of laudanum; by breathing for her four hours with the face-mask alone, her life was saved, *i. e.*, without tracheotomy.

Now comes a case which I want particularly to call your attention to, as one in which some facts were demonstrated which I had been waiting for for a long time. Dr. Wood, while admitting that I made the first comprehensive op-

eration of forced respiration, criticized the apparatus used, and in reply to his objections I desire to state that when I made my first operation it was with incomplete apparatus, and it was surprising on this account that I did not lose the case. Had I failed it would probably have "settled" the question of forced respiration. Before, however, attempting to construct a suitable apparatus, I very carefully considered the details and the conditions to be met, and the apparatus as finally devised consists of a tracheotomy tube, a tube connected with the air-control valve, and then a tube connecting that with the air-warming apparatus, which in turn is connected with the bellows by another tube. With this apparatus, whether on board of a ship, or even on the ice, or elsewhere you can supply the human lungs with air at the temperature of the body within five or ten minutes at the most from the time you begin, and can keep it up for an unlimited time. So it will be seen that while my apparatus covers almost all the conditions for every case that may present, yet it also answers for the *most simple method possible* in forced respiration. That is, you can use the face-mask, rubber connecting tube and bellows alone, or the face mask, air control valve and bellows alone, which I would by all means recommend as much better than the former combination. In this last case, a woman had taken an uncertain amount of morphia—a large amount, however, as was evident from the effect produced upon her. About midnight a physician was called, but refused to attend, so that she was under the influence of the narcotic all through the night, until about 10 o'clock the next morning. I was called at 9 A.M., and arrived about 9:30. I ascertained there was no pulse at either wrist, but on auscultation found the heart faintly acting, cyanosis deep. I then had her placed upon a mattress in an adjoining room, and with the face-mask, air-control valve and the bellows, went to work. I digress again to state that the point of interest in connection with this air-control valve is this, the moment you press the lever the air passes into the lungs; release it, air can pass out of the lungs, or it can pass into the lungs (though not from the bellows), or auto-respiration can take place. The moment the valve is pressed down, though the bellows may be ten or twenty feet away for that matter, yet the air is under continual pressure, and enters the lungs from the valve without any loss of time. You have absolute control of the air passing to the lungs; and this is the important factor in the whole proceeding. (Also in the use of the valve, as improved oxygen can be systematically administered). If you had the bellows and the face-mask alone, the air would necessarily have to come clear from the bellows, through the tube, to the face-mask, before you could be sure of its passing into the

lungs, and consequently the respiration could not be carried on so satisfactorily. Dr. Vandenberg's apparatus operates, I believe, so that when you work the bellows air passes into the lungs; but when you stop the bellows, the flow of air ceases; and I do not think there is as quick control of air passing to the lungs as by the method I have used so satisfactorily. Furthermore, all the physician has to do is to work the air-control valve, and any one can work the bellows, which is the work in which physical exertion is expended. In the case now under consideration, I worked for fully an hour and a half before the pulse at the wrist could be detected. The woman then became conscious, sat up and asked for a drink.

In the middle of the afternoon, Dr. Porter came in to witness the operation and offered his assistance, which was accepted. It may be stated that when a person is very deeply narcotized, with forced respiration we may occasionally produce a conscious condition, but the patient will again pass under the influence of the narcotic, and become utterly unconscious. You may breathe for him or her for half an hour at a time, yet there will be no evidence of life except the action of the heart and the fact that the blood is supplied with oxygen. So this lady would occasionally become conscious. During one of these conscious periods Dr. Porter, who had been standing in one corner of the room, came forward and began to perform Sylvester's method of artificial respiration—with the object, I presume, of demonstrating that it would accomplish as much as what I was doing. He understood how to apply that method from previous experience. All watched the result with interest. In a little while, the cyanotic condition began to appear along the face, gradually becoming deeper and deeper. I said, "Doctor, you see now just what the result is." "Yes," he said, "there is no question about it." We then renewed the forced respiration with the face-mask. In a short time the cyanotic condition disappeared, and the woman again became conscious. I regard it as a very important and interesting fact to state, therefore, that we had here a demonstration that forced respiration with the face-mask will accomplish more than the best of the methods of artificial respiration in use in the past throughout the world. You can save life by forced respiration by this method when you cannot possibly do it by any method of artificial respiration whatever. I kept up forced respiration with this woman until she revived again, and began to be in quite a jovial condition, and as I thought, was perfectly safe. Then Dr. Porter desired to try the Faradic battery, which I consented to, regarding the woman's condition such that, were it necessary, we could at any time rely upon the forced respiration again. I was anxious, of course, to report this as another case of life saved by forced respiration. After

breathing some eight hours and carrying the case through the most critical period, we called the Faradic battery into play. But what is the result of faradization in a case of that kind? Merely the stimulation of the heart at the expense of its energy. However weak the current may be, if you obtain any heart action, it is of a tonic nature, and secured at the expense of the energy of the heart muscle. What we need to look out for in such a case is to conserve the energy and the vitality of the heart muscle. In this case the result was that after about three-quarters of an hour of faradization the heart stopped beating, spasmodically. The case was lost through faradization.

Now, a moment to consider the relative value of tracheotomy and of the face mask in forced respiration. Is tracheotomy any better than the face mask? Prof. Wood, of Philadelphia, says he does not think it will ever be necessary to resort to tracheotomy. My belief is, founded on this last case, that in a long continued operation it is possible to breathe for the patient more easily and thoroughly by resorting to tracheotomy. In respiring for a person with the face-mask, it must be remembered that the passage to the stomach is open, and the air passes down the oesophagus to stomach and intestines. This presents the difficulty in working with the face-mask. If it is desired to eliminate poisons the patient may be given anything without danger of fluids passing into the trachea, by the tracheotomy method; and you have better control of the patient. If I had a case in which I thought I should have to respire for the patient for eight or ten hours or more, I would make tracheotomy, feeling that I could accomplish more, and have more thorough control of the patient.

I do not recommend as yet intubation, because I think there are many cases, in fact have seen many, where it was not practicable owing to the difficulty of intubating the larynx; and if we can pass air into the larynx or trachea without intubation, as by the face-mask, it is of course always better to do it. This is my opinion, from the experience derived in operations on a dozen living beings.

In these experiences I have encountered, I think, quite a number of facts bearing upon the treatment of opium narcosis which are both new and valuable; but I will not refer to that at the present time. I merely wish at this time to call attention to the interesting fact that with the face-mask and forced respiration more can be accomplished, as I believe, than by any method of artificial respiration; and the widely accepted dictum of Marshall Hall that we must use no forcible measures, leads me to give unusual emphasis to this statement.

I will merely add, in closing this inpromptu talk, that fifteen lives are so far to be credited to

the operation of forced respiration. When it comes into general use in cases of drowning, shock, the tiding over of critical cases, in asphyxia from whatever cause, as well as from narcotic poisons, who will not admit it is one of the most important procedures at our command?

MORVAN'S DISEASE: WITH THE CLINICAL REPORT OF A CASE.

Read before the Chicago Medical Society, March 2, 1891.

BY ARCHIBALD CHURCH, M.D.,

PROFESSOR OF NEUROLOGY IN THE CHICAGO POLICLINIC, ETC.

The first description of the diseased state which by courtesy and for convenience may be called "Morvan's disease," was made by Dr. Morvan, of Lannelis, in Brittany, and published in the *Gazette hebdomadaire de Médecine et de Chirurgie* in 1883, under the title of "Parésie Analgésique avec Paralysie des Extrémités Supérieures." Since that date he has made numerous communications on the same subject in the same journal, with the reports of eighteen cases. In 1885 M. Broca (*Ann. de Dermat. et de Syphillog.*) published a case, and in 1887 M. Prouff (*Gazette Hebdom.*), another Breton physician, recorded one, followed by Hanot in the same year. In 1888 d'Oger de Speville collated in a Paris thesis nine cases from various sources. In 1889 Heckel published a clinical observation (*Berlin Klin. Wochenschrift*). The same year (*Sem. Méd.*), Gombault reported the autopsy of Prouff's case before the Société Médicale des Hôpitaux de Paris, and in 1890 Charcot (*Prog. Méd.*) published a clinical lecture on the subject, to which the writer is mainly indebted for the following description and for cuts 1 and 2.

A majority of the recorded cases have been among the Breton peasantry, but the condition was first observed in that locality, and possibly is as frequently found elsewhere, though not recognized under this name or as a disease of the central nervous apparatus. Morvan's attention was first attracted by finding a painless whitlow. In his first paper (1883) he says:

Twenty-five or thirty years ago a man of 60 presented himself, with a whitlow on one of his fingers. We made out a necrosed condition of the ungual phalanx and proposed to make an incision and extract the bone. As the patient gave his permission with reluctance, he was assured that the incision would be made like a flash, so that he would not have time to suffer. The cut, which was sufficiently free, was accordingly made, but what was our amazement to see the calmness of this man. Not a complaint! Had he been of wood it would have been quite the same. He affirmed that he had not suffered at all. . . . Taking a pin, we thrust it into various portions of the hand and forearm, which were swollen, without causing distress.

Originally Morvan stated the three characteristics of this condition to be, 1. Initial pains of a neuralgic sort in the extremities; 2. The appearance of paresis and analgesia, mainly in the hands; 3. The appearance of successive painless and destructive whitlows. Subsequently he modified this dictum, as cases fell under observation in which sensation was not materially changed, or in which paresis was absent, so that the only characteristic to be insisted upon is destructive and numerous whitlows.

The disease has numbered more men than women, but the few cases recorded do not justify generalization in this and many other particulars. Instances have been noted at all periods of life from twelve to sixty years, and for the most part occur in individuals exposed by out-door avocations. As it is the lower portion of the cervical enlargement that is primarily and mainly affected, the exposure of the neck by these people to the inclemencies of the seasons may be worth noting, *en passant*, as a predisposing factor.

The tangible clinical points of any one case are rather meagre, and, owing to the essentially chronic and progressive course of the malady, the early phases are often left in doubt through the forgetfulness of the patient. Frequently there is a history of neuralgic pains of long duration in the extremities afterwards affected, and this is followed by weakness. Sooner or later a felon makes its appearance and, depending upon the condition present as to analgesia, is painful or absolutely free from discomfort, though the swelling, redness and ulceration may attain a destructive grade. Indeed, the tendency of these inflammatory disturbances is to produce more than an ordinary amount of destruction and mutilation. There is usually exfoliation of a part or the whole of the terminal phalangeal bone, and the upper ranks are not infrequently lost. The nail matrix is also affected, resulting in dwarfed, claw-like nails, or only slight horny protuberances may be left. When the analgesia is pronounced, an apparently exquisitely tender felon may give no pain upon manipulation and, as we have seen, not even resent the knife. In this condition the patients have frequently themselves picked out the bony fragments, the slight discomfort not leading them to seek surgical aid. Such fingers present a characteristic appearance. They are short and thick, and if the middle phalanx, or more emphatically if all the phalanges are lost, the presence of the stunted nail at the end of the stump is sufficiently noticeable. It appears as if the finger had been telescoped. (Cuts 1 and 4.) In some cases other evidences of dystrophy are present. The flexures of the fingers and the palmar folds are liable to cracks and fissures which are difficult to heal, and may present thickened epidermic margins about an indolent ulcerated centre, comparable to perforating ulcers of the

feet due to nerve injury, and not rarely found in tabes dorsalis. While the first felon may be painful, and marked by all the misery that usually attends them, succeeding ones are not, and, as a rule, both hands are eventually invaded. In one of Morvan's cases the lower extremity was finally implicated. Cases present from two to ten successive whitlows, and every digit may be mutilated by them. The tendency is to their symmetrical distribution. The hands become cold, dry, and subnormal in temperature, or may be the seat of profuse sudation and chronic swelling. Broca called attention to the fact, confirmed by Morvan, that the spinal column in over one-half the cases showed by distortions the tendency to dystrophy in osseous structure. The scoliosis or kyphosis, however, is usually slight in degree, and not accountable for any injury to the spinal cord. Indeed, it is a result of the implication of the cord, and another evidence of the impairment of the cord's trophic functions. As a rule, the convexity of the curvature is toward the hand

cases the body is invaded more or less widely. The forearms and hands often present considerable muscular atrophy, and to the electric current manifest changed reactions indicative of nerve degeneration. Superficial and deep reflexes are not noticeably changed, nor is coordination materially modified.

Gombault's autopsy of Prouff's case furnishes all that is known of the anatomy of the disease, with the exception of some minor observations made upon the amputated extremities of the fingers, which furnished evidence of peripheral neuritis. This, the only case completed by an autopsy, was a woman of 56 years, who from the age of 12 had suffered from a series of whitlows which had caused considerable mutilation, marked by trophic troubles of the skin and muscles with errors of sensibility, all located in the hands. The spinal cord and peripheral nerves of the upper extremities were particularly examined. He says:

The nerve lesions consisted in an exaggerated production of connective tissue, with degeneration and disappearance of a large number of the tubules. These lesions presented the sort of distribution attributed to ascending neuritis; that is to say, they were more marked at the periphery and gradually diminished as the body was approached. In the spinal cord the alterations were localized in the cervical region, and only implicated the posterior horns, the posterior columns, and a small portion of the central gray substance. All these parts were the seat of an abnormal and diffuse development of interstitial tissue with thickening of the arterial walls, and frequently with obliteration of the lumen of the vessels. Nowhere did this sclerosis assume the form of an isolated or separable tumor. Owing to the state in which I found the cord when I was enabled to examine it, I could not decide whether there existed accidental cavities in the middle of the central gray substance, analogous to those which characterize syringomyelia, or not. I am, however, rather inclined to admit the negative. Nor can I decide whether the cord change had been the cause, or only the result, of the lesions in the nerves. The single point to retain from this examination, it appears to me, is the co-existence of lesions pertaining both to the cord and to the peripheral nerves.

No. 1.—Hand in Morvan's disease. Hanot's case. After Charcot.

No. 2.—Hand in Scleroderma. After Charcot.

first involved, which is generally the right in men, the left in women. The joints of the hands, wrists, elbows, and even the shoulders, are sometimes affected with a dry, painless arthritis, and a condition analogous to the joint lesions of locomotor ataxia is developed. (Cut. No. 3.) In several instances a slightly subnormal temperature has been persistently recorded even during inflammatory features of the malady.

Aside from the analgesia already mentioned, and which seems primarily to affect the deeper structures, there are usually well-marked and various impairments of cutaneous sensation. Tactile, pressure and thermic sensations, severally or singly, may be diminished or obliterated, or intact. No mention is made of hyperesthesia, but the persistence of tactile sense with the complete loss of thermic and painful impressions, is said to be rarely or never present. The extent of these perverted areas of sensation seldom passes above the upper extremities, though in some

It was on the same occasion pointed out by Debove that these lesions bore a striking resemblance to those of tabes. Charcot agreed perfectly with Morvan that the trouble is primarily in the cord, and that the trophic and sensory disturbances and the peripheral neuritis are all secondary to the central change, while others find an explanation of the cord lesion in the extremities and the pathological conditions found there. It is needless to say that as yet, no microbe has been brought forward as an etiological factor, and the ultimate cause of the disease is wrapped in the same mystery which pertains to other sclerotic affections of the cord. Even syphilis has not been accused of the paternity of this malady.

The diagnosis of the disease in recent cases must often be difficult, but when the condition has been of long standing it is probable that ordinary attention and care, with a knowledge of

its existence, will be quite sufficient for its recognition. A somewhat allied tropho-neurosis, localized and symmetrical scleroderma, may at first be confusing. When this condition is limited practically to the hands it gives rise to paresis, distortion and changes of a general nature in sensation, with atrophy, but there is no tendency to alteration, to the exfoliation of bone, and the peculiar analgesia above described as usual in Morvan's disease is wanting. The hand assumes a peculiar position with the digits extended, except at the metacarpo-phalangeal joints, which are flexed, and there is a tendency to over-extension in the middle joints of the fingers, particularly in the index. It is the arrangement produced by the action of the interosseous muscles, and is sometimes called the interosseous position. The skin is shiny, adherent to the bones, and the digits, atrophied *en masse*, behave like so many tapering rigid sticks. (Cut No. 2.) Associated with scleroderma is a peculiar mask-like expression of face, due to the implication of the facial integument and its adhesion to all bony prominences. This is so characteristic that, once recognized, it can scarcely be mistaken.

Another form of scleroderma, *ainhum*, occurring almost invariably in hot climates and in the dark-skinned races, may produce painless amputation of fingers and toes, but usually is limited to the feet, and it is the outer toe that is lost, as a rule. In this condition, the history of a slowly forming constriction by a cicatricial-like encircling band will prevent mistake.

In the anæsthetic forms of leprosy the nails, portions of the fingers or entire digits, may be lost without pain or local suffering. This insensibility is due to a peripheral neuritis set up by the bacillary infection upon which the disease depends. The condition is distinguished from Morvan's disease by the history of exposure to leprosy, and the disseminated leprosy nodules and patches on the integument of the body. The process, moreover, is the reverse of the loss of a finger from whitlow. An abrasion of the skin becomes an ulcer, grows deeper and wider, encircles the finger or envelops it completely, and finally causes its destruction or leads to its amputation by the surgeon.

Symmetrical gangrene or Raynaud's disease, so rare a condition that Billroth, a few years back, had never seen a case in his unparalleled field of observation, though sometimes causing a loss of fingers, presents a totally different picture from Morvan's disease. The digits affected, upon exposure to cold or in the morning, or after emotional excitement, present a blanched, shriveled, purplish or mottled appearance, with sensations of tingling and numbness, a loss of power and considerable discomfort. This passes away in a short time or may persist for hours, to recur under similar circumstances for months or years. Sub-

sequently, in destructive cases, the circulation, which is said to be inhibited by vaso-motor spasm, does not become even temporarily restored, and dry gangrene results, causing mummification of the members and finally their loss. There is no whitlow, no peculiar dissociation of cutaneous sensations, and no evidence of organic cord disturbance before or after death.

Some writers and observers, with Debove in the lead, assert that Morvan's disease is identical with syringomyelia, but this is most vigorously denied by Morvan himself, and he is supported by Charcot, Hanot and others. Nevertheless, there are many striking clinical resemblances. The asserted pathognomonic indication of syringomyelia is loss of painful sensations and inability to distinguish the temperature of any object brought into contact with the affected areas, while the sense of touch and tactile impressions remain essentially unimpaired. It is often associated with atrophy and paresis depending upon the distribution of the gliomatous infiltration about the central canal of the cord, which forms the anatomical basis of the condition and gives rise to the cavities within the cord and the dilatation of its central canal upon which the somewhat unwieldy name depends. Morvan insists that this particular dissociation of the cutaneous sensations is never found in the malady bearing his name, and the single post mortem observation already quoted does not correspond with the findings in cases of syringomyelia now on record. However, both Morvan's disease and syringomyelia number but few published complete instances, and it may be premature to insist upon their absolute differentiation. To an unprejudiced mind the prime point of importance is the fact that they both depend upon an irregularly distributed sclerosed condition of the cord. The variations outside of that seem to be a matter dependent only upon the position of this adventitious and unsystematized lesion as it affects nutrition, sensation and other myelic functions in proportion to their anatomical implication. Besides, all gradations between typical syringomyelia and typical Morvan's disease have been encountered. Both are instructive in demonstrating the location of sensory tracts in the cross section of the cord. The clinical and anatomical features of resemblance between tabes dorsalis and Morvan's disease have been already pointed out.

The course of the malady, as already often indicated, is extremely chronic, and as far as now known, practically beyond the influence of therapeutic intervention. In any given case it is to be expected that whitlows will occur from time to time, and of course the resulting mutilations are irreparable. In some instances, from this source, septicæmia has resulted and terminated life. Such measures as are directed against a low grade of inflammation in the cord are to be tried

and persevered with, and of course the general health is to be maintained. It would seem specially advisable that the hands receive scrupulous care and protection, as any traumatism or superficial abrasion may cause serious results or even lead to the loss of a finger.

The following case was brought to the writer's attention by Drs. Patrick and Harris, of this city, and of the Policlinic staff, in November, 1889, for an opinion regarding the nature of the joint disease in the left wrist (Cut 3), its similarity to the joint lesions of locomotor ataxia having given rise to discussion. At that time undue weight was attached to the scoliosis, which is marked (Cut 5), and implication of the cord or nerve roots was suspected. Further consideration of the case enables one to classify it with those recorded under the title of "Morvan's disease," every important symptom of which it presents, besides some additional features not incompatible with such diagnosis. Since that date the man has been casually seen at intervals, and nothing new has developed. Recently (January, 1891) a careful and thorough examination has been made and photographs obtained, from which cuts 3, 4 and 5 are reproduced.

No. 3.—From a photograph. Hand in Morvan's disease, showing joint lesion.

Case.—A. N. is an unmarried Swede of 35 years, who has been in this country since 1886. He now makes a fair living by taking orders about the city for a tobacco firm, in which occupation he does much walking, and is in the enjoyment of excellent physical health, confirmed by his general appearance. His family history presents, as far as he is informed, absolutely nothing in the way of a neurotic trace, and his parents both attained a very advanced age. As a child,

youth and young man he was always in good health, growing up in the country. He was engaged in farming until he came to America. Owing to the poverty of the family and the barrenness of the land, his life was one of extreme labor and hard-ship. His habits have been exceptionally good in all respects, and there is neither history nor trace of any venereal infection. He states that some ten years ago his back became crooked. Previous to that time he asserts that he was as straight as any one. About the same period he had a felon on the right ring finger, near the extremity on the palmar surface, which was excessively painful, kept him awake nights, was marked by high inflammation, great swelling, deep-seated suppuration, and which has left the finger stunted, with a deformed nail and shortened distal phalanx as shown in cut 4. Six years ago, after a bath in a lake on a cold day, he drove several miles in a cold wind, and in a day or two the left hand, wrist and arm became greatly swollen and very painful. He was sick, confined to his bed for a month, and remembers having severe chills and a high fever. The swelling in his wrist, where the main difficulty was located, never entirely subsided, and now presents the contour and deformity shown in Cut 3. There is no pain, heat, redness or tenderness about the greatly enlarged joint, though the carpus seems entirely disintegrated. Upon passive motion, which is but slight, there is roughness, grating and creaking in this articulation. The thumb is shortened as is the entire hand, and seems to articulate directly with the radius. Its extremity does not reach the first phalangeal joint of the index, as it should normally, by nearly an inch. There is a subluxation of the entire metacarpus forward, and spastic flexion of the fingers, which cannot be straightened voluntarily, and passively only by the employment of considerable force. The whole hand is diminished in thickness and width, and the fingers present a delicate appearance out of keeping with the rest of the extremity, which is rather muscular. The integument is somewhat smoother than usual, but these points may be due to the comparative disuse of the hand for heavy work. The extensor tendons of the fingers are salient on the back of the hand, and the intrinsic muscles seem wasted. Over the thumb he has good control, and the thenar eminence is full and round. Although the grasp of the hand is very much reduced, it is a useful member, capable of many complicated and fine manœuvres.

Three years ago he lost the end of the right index by what he describes as exactly the same process which ten years ago attacked and mutilated the right ring finger, with the very extraordinary exception that it was absolutely painless and not even marked by tenderness. He states that the finger was enormously swollen, very red and angry looking, finally discharging pus, and

that he himself picked out of it several fragments of bone. As shown in cut 4, it now presents but a small portion of the middle phalanx, the distal bone being completely absent, and the greatly deformed, horny, nipple-shaped nail is seated upon the end of the stump. The scar marking the opening through which the bones escaped is on the anterior surface, running to and involving the nail matrix.

No. 4.—From a photograph. Hand in Morvan's disease, showing mutilation from whitlows.

Within that same year the middle finger of the right hand went through exactly the same programme and exhibits practically the same mutilation, though even more shortening is present. In both these fingers the joint between the first phalanges and the fragments of the second is preserved. The hands show no other trophic disturbances. The skin is elastic, soft, properly moist and of a good color, indicating no material change in the circulation of the parts, nor are they unpleasantly affected by cold weather.

Upon testing the sensibility of the hands it is found that on all parts the lightest touch with a flake of cotton wool is instantly perceived and accurately located. Indeed, he responds to this delicate test better than some individuals in a presumably normal state of health. The prick of a pin is equally well felt, but not as a painful sensation. He cannot detect the difference between a pin point and a blunt pencil, and this too when the pin is thrust sufficiently into the skin to remain standing there. When tested with similarly shaped hot and cold objects it is only with difficulty that he can properly make out their respective temperatures, and slight variations escape him entirely. These peculiar conditions are present in all portions of both hands and gradually fade

out upwards toward the elbows. There is no retardation whatever in the transmission of tactile impressions, and no subjective unnatural sensations. Palpation does not detect any tenderness over the nerves or thickening of their trunks. Co-ordination in the upper extremities, as tested by having the patient make exact movements of wide range while his eyes are closed, is quite normal, and electrical tests present no departure from the formula of health, even in the left hand. The muscular sense seems normal.

No. 5.—From a photograph. Showing scoliosis in Morvan's disease.

His gait is somewhat shambling and difficult to describe, being more of a peculiarity than anything else. There is no limp or dragging of the feet, and he walks in a straight line with great precision and firmness with his eyes closed. His body is plump, smooth and free from blemish of any sort, but the spinal column shows a compound curvature. The convexity, beginning in the upper dorsal vertebrae, is backwards and to the right, embracing most of the dorsal region, with a compensatory curve in the opposite direction in the lower dorsal and the lumbar spine. These curves are practically very pronounced exaggerations of the normal lateral deflections, and certainly not sufficient in themselves to implicate the cord, the lesion of which, indeed, cannot be below the first dorsal segment. They may explain the peculiar walk. There is no tenderness anywhere along the spine or any marked prominence of the spinous processes, and the column is ordinarily flexible throughout. In taking the photograph from which Cut 5 is made, the outline of these

processes was indicated by roughly marking them on the patient's back with iodine.

An examination of deep and superficial reflexes detects nothing abnormal, though the knee jerk is somewhat pronounced. There has never been any loss of control over the bladder and rectum, or difficulty of any sort with these organs. There is likewise nothing in the history suggestive of the lightning pains and crises of locomotor ataxia, nor girdle pains, nor hyperæsthesia of any character. The special senses and their respective organs are quite normal, the mind unaffected.

In summing up the case the analgesia in the hands, the dystrophy of the wrist-joint, the loss of fingers by whitlows, all point to the diagnosis of Morvan's disease and furnish its most salient characters. The retention of the tactile sense with the marked blunting of painful and thermic impressions, *per contra*, constitute the so-called pathognomonic indication of syringomyelia. This therefore is probably a mixed case. Such a number of speculations as to the exact location of the lesion in the cross section of the cord present themselves, that their discussion is idle. This much seems certain, the anterior horns and the pyramidal tracts are not implicated. The solution must be left to a post-mortem examination which, fortunately for the patient, appears to be a distant contingency.

167 Dearborn St., Chicago.

ABSCESS OF THE LUNG.

Read before the St. Louis Medical Society, December 14, 1890.

BY WILLIAM PORTER, M.D.,

PROFESSOR OF DISEASES OF THE THROAT AND CHEST IN THE ST. LOUIS COLLEGE OF PHYSICIANS AND SURGEONS.

I have not thought to present an exhaustive essay upon this theme. The subject is interesting, its literature comparatively meagre, and it is closely related to the progress of that most aggressive department of our science—surgery; so that at least I may offer a few conclusions regarding it for your discussion.

Permit me at the outset, by way of definition, to say that it is not intended in this paper that the term abscess should apply to those accumulations of pus secreting cavities which are so often found in the later stages of phthisis, but only to the circumscribed suppuration which may arise independently of tubercular processes. The history of pulmonary abscess as given by the older writers is not very exact. They generally supposed that the condition was the result of delayed resolution of pneumonia, and that if the inflammation did not subside by the twenty-first day suppuration was sure to result. This latter proposition is not in accord with modern knowledge, yet we do find that abscess is often preceded by a pneumonia more or less severe. Stokes places abscess as the fifth and last stage of pneumonia,

while Leyden further recognizes a form of chronic abscess, occurring in chronic pneumonia, resembling the vomica of phthisis. While there may be many causes that predispose to pulmonary abscess, the positive causes aside from traumatism and foreign substances are easily placed in three classes: 1. Inflammation within the lung; 2. Perforation of pus cavities from without, as for instance, from the liver or pleural sac; 3. Embolism from right endocarditis or from the systemic veins. I believe also that we may sometimes have the first and third conditions combined. In croupous pneumonia, for instance, there is not only the local inflammation within the pulmonary structures, but often a marked depression of the vaso-motor system and of the motor ganglia of the heart. As a consequence there is in addition to the local pneumonia, a distension of the pulmonary vessels, oftentimes of the right ventricle itself, and greatly diminished circulatory force within the lung, conditions that must favor obstructions in either the bronchial or pulmonary system with destruction or infection of the tissues beyond the occluded point. Several cases of circumscribed abscess of the lung that I have examined closely gave no evidence of preëxisting pneumonia, while everything pointed to the hypothesis that the local lesion was the result of infarction from embolism.

A few points in the etiology of pulmonary abscess may be noticed in passing. The first is the statement found in most of our books upon the subject, that local inflammations in the lung cause the single abscess, while the results of embolism are multiple. Not always is the latter proposition correct. There certainly may be a blocking up of a single branch of a bronchial artery from embolism, sufficient to cut off all supply from that portion of the pulmonary structure beyond, causing gangrene; so also we may have a single branch of the pulmonary artery plugged by an infectious embolism, and consequent infarction and the disintegration of the surrounding structures.

A second thought closely associated with the etiology of pulmonary abscess is the fact that while occlusion of a bronchial artery is more likely to produce gangrene than an occlusion of a pulmonary branch, yet the latter conditions may also cause gangrene by the infarction and often consequent apoplexy, destroying the bronchial circulation and thus cutting off nutrition.

While then we may believe that an embolism in either the bronchial or pulmonary systems may produce gangrene, is it not also probable that an embolism in a bronchial branch may produce an abscess? The fragments from this form of endocardiac inflammation are known to have septic properties and to lead to suppurative infarctions. Why not in a small bronchial artery as well as elsewhere?

Again, we may ask the question as to the relation between a slowly resolving pneumonia and pulmonary abscess. Generally the influences of the local inflammation may be directly the cause of the consequent suppuration and we nearly always find the abscess at this site of the pneumonia. I believe it possible, however, for septic material to be carried from the lung itself, during the processes either of suppurative pneumonia or pulmonary tuberculosis, to pass from the pulmonary venous system through the left heart into the aortic and by way of the bronchial arteries back into the lung, and so producing infarction and infection. My reason for this hypothesis is the result of an autopsy in a case of croupous pneumonia, which had become suppurative, and the finding of a hæmorrhagic infarct and tissue degeneration in the opposite lung, in which were no post-mortem evidences of pneumonia.

Believing embolism, either of a bronchial or pulmonary arterial branch, to be a frequent cause of abscess in the lung, I would not underestimate the effect of local inflammation in the lung as a causative agent, for after all, most of the cases of abscess are the result of such conditions. This is what we might expect where restoration to the normal is delayed, especially after pneumonia. In the croupous type, and indeed, in the catarrhal also, the epithelial lining of the vesicle is destroyed, and if a suppurative process follows incomplete resolution it is not hard to understand how the pus-bathed vesicular wall, with impaired blood and nerve supply, may break down and the vesicles coalesce in abscess cavities.

The close parallelism which exists in the etiology of abscess and that of gangrene is also found in the study of the pathology. It is claimed by some that where the abscess is the result of embolism, that in the obstructed vessel are found specific micrococci having pathogenetic or pyrogenetic force. Ogston found microorganisms present in a large number of cases of abscess of the lung, and other observers have made the same statement. In one case I found large colonies of the bacillus tuberculosis, the abscess being undoubtedly tubercular, although the rest of the lung was not infected so far as could be determined. After the destructive tendency has been once established the conditions of progress do not vary much from what is known of abscesses in any soft tissue. The main difficulty in the diagnosis of pulmonary abscess is its oftentimes close resemblance to gangrene. It is fortunate for us that it is not necessary to establish positively the existence of one or the other, in reference to treatment. Whether it be a simple abscess, destructive gangrene, or, as often happens, gangrene with liquefaction, the indications for interference are generally plain enough.

I need not long detain the members of this

Society in discussing the diagnosis of abscess of the lung. If in addition to the physical symptoms of localized dulness and absence of vesicular murmur, we have the sudden appearance of large quantities of pus in the expectoration, an abscess may be suspected, especially if we find the presence of the elastic fibers of the alveoli, in addition to brownish red pigment and hæmatoid crystals. The absence or presence of these substances, as well as the history, will do much toward determining the differential diagnosis between abscess of the lung and pus cavities penetrating the lung from without.

Many writers have thought that the main physical symptom in making a diagnosis between extra-pulmonary cavities and those within the lung was the pectoral fremitus. Fremitus is often absent where the abscess is outside the pulmonary tissue, and increased over an intra-pulmonary cavity communicating with a bronchial tube, and partly filled with liquid, but in a paper by Fenger and Hollister in the *American Journal of Medical Sciences* for 1881, they concede the doctrine so far as consumptive cavities are concerned, but doubt whether it is true in cases of abscess or gangrenous cavities. In several cases that I have examined, where the diagnosis was afterwards confirmed by operation, the pectoral fremitus was greatly increased. The diagnosis between abscess and gangrene is not easily made so far as the physical symptoms are concerned, but the more marked depression, the horribly characteristic odor, not only of the sputum, but of the breath, and the greyish green expectoration of gangrene will not be easily forgotten. The lower layer of the sputum from gangrene, when allowed to stand, contains peculiar plug-like structures called "mycotic bronchial plugs" by Eichorst, from which Jaffe obtained a snow-white substance which turned blue when iodine was added, but which was neither albuminoid nor saccharine. He and Leyden gave this fungus the name of "leptothrix pulmonalis," resembling as it does the leptothrix buccalis. This cannot be estimated as an unailing evidence of gangrene, as the same fungus is found in the sputum of other diseases when allowed to putrefy.

When an abscess of the lung has been recognized, the manner of treatment is a worthy subject for discussion. Shall we, in the words applied to other conditions by the venerable Dr. Boissiniere, "maintain a masterful inactivity" or shall we formulate expectant measures for relief, or shall we go still further and undertake active surgical interference?

There are certain conditions which must be considered before these questions are definitely answered. It must be remembered that it is not impossible that a pus cavity with such free exit as exists in the lung may fully empty itself, and the walls contract and cicatrize. Much depends upon

the character of the general symptoms. If there is free expectoration, little interference with respiration, absence of pyrexia, and nearly normal pulse there may be no great danger in delay. These conditions are exceptional, however, and the temperature and the pulse, as well as the quantity of pus expectorated, point to rapid disintegration which calls for active treatment. The location of the abscess may have something to do with the question of treatment. Fortunately the direct danger from suppuration is not great. The large vessels and nerves are well to the median line, except in the upper part of the chest, and abscess in a lower lobe is comparatively easily reached. Just here let me say that contrary to the statements of many of our best authors, I have not found abscess of the upper lung even comparatively frequent, except in tuberculous cases. Nearly all of the cases of which I have notes were found in the lower lobe, and generally on the left side. I would not, however, place the experience of a single observer in opposition to the aggregated result of many.

The size of the abscess cavity may be an important consideration in determining the treatment, while we might be willing to wait the further development where the lesion is small and non-aggressive, yet we would not procrastinate in cases of opposite conditions. I believe it is a recognized principle in surgery that when there is pus it should, if possible, be evacuated. That this principle should apply to pus in the lung as well as elsewhere is a reasonable conclusion, not only theoretically, but as a deduction from practice. Even in cases where the abscess is small, where the general symptoms are mild and the local disintegration limited, it is a question as to whether the abscess should not be treated as it would be did it occur in any other part of the body within reach.

But where there is evidence of rapid breaking down of the lining structures, where the general symptoms of fever, restlessness and great depression are prominent, it seems to me that there can be little doubt as to what should be done, and done quickly, lest there be further infection from the pus cavity. The indications for operation may not, however, apply to tubercular cavities if there be general pulmonary infection.

Where there seems to be a demand for removal of the pus, we may ask with Fenger and Hollister, "Is the cavity so situated that we may get at it from the outside, and is the pleural cavity covering it obliterated by adhesions, so that we do not run any risk of causing a fetid pyo-pneumothorax by opening into the abscess and allowing the decomposed matter to enter the pleural cavity?"

The surgeon of to-day who removes ovaries from the abdomen and tumors from the brain, would scarcely hesitate to explore any part of the thorax did he have a reasonable prospect of good

result. Certainly the largest part of the lung below the mammary and axillary regions are within reach of the exploring needle, and if need be, the knife.

The second question is of serious import; for surely we would gain little did we but transfer the infectious pus producing process from the lung to the pleural sac. There is comfort in the thought that if the abscess be large and near the surface, there are often adhesions obliterating the pleural cavity and removing the danger in this direction. The authors above referred to assert that it is quite possible to determine the existence of adhesions by making an incision down to the intercostal muscles and passing a needle through both pleural walls. If the needle moves synchronously with the respirations, there are adhesions; if not the pleural walls are not adherent and the operation may be abandoned.

The above is a valuable suggestion but the conclusion may be modified. Under no circumstances would I abandon an operation for pus so situated, unless the life of the patient were in immediate peril. The fact of a non-adherent pleura may change the character of the operation, but the desired result should be obtained in the evacuation of the pus.

When the necessity for surgical treatment is apparent, there still may be a question as to the nature of the operation. Mosler, some twenty years ago, drained a superficial tubercular cavity through a silver tube. Fenger, a decade later, recommends a double soft rubber drainage tube, and both of these avoid resection of the rib. I believe that a better operation, especially where the abscess is large and low down, is to excise a large piece of the rib directly over the cavity and make a free opening into the pleural sac. This free opening into the serous chamber not only does away with the danger of subcutaneous emphysema but enables us to keep the pleural cavity thoroughly aseptic and lessens the difficulty spoken of by Fenger and Hollister, where there are no adhesions. If the cavity be large, the excision of the rib is better for the same reason that it is almost necessary empyema in that it permits a quicker and better closure of the abscess cavity. This is the method advocated by Ruenberg, of Sweden, and adopted by some of our best surgeons, although others object to the excision of the rib on account of possible periostitis and necrosis.

After the pleural sac has been freely opened a much smaller incision may be made into the pulmonary tissues. Within the lung, even at the base, are arteries and veins sufficient to cause considerable hemorrhage, which may be difficult to control. Sutton warns against plunging the knife into the lung, and Fenger suggests a small opening made by a trocar gradually dilated by blunt instruments till large enough to admit a good sized soft rubber tube.

As the patient will necessarily remain in bed for a considerable time the opening should be made far back on the side to allow free drainage. The tube may be kept in place by a safety pin passed through its outer end and fastened to an adhesive strip. An absorbent compress and bandage will not only take up the pus which will continue to come away for some time, but will prevent the exit and entrance of air during respiration.

That the operation is justifiable is shown by the record. In 1881 Fenger and Hollister reported six cases, one of which, their own, recovered, and Ruenberg (*London Medical Record*, 1887) collated eleven cases of abscess. Two recovered and in three cases the diagnosis was doubtful. In the three fatal cases death could not be attributed to the surgical operation. In seventeen cases of gangrene collected from medical literature, where pneumotomy was performed, seven recovered more or less completely (*Annual of Medical Science*, 1888).

Permit me to offer an abstract of the history of two cases of gangrenous abscess of the lung seen during the last year.

Case 1.—Mrs. G., of North Eighteenth street, a young married lady of good family history. I first saw her in March, 1890, in consultation with her family physician, Dr. A. S. Barnes. The statement was made that she had not been well since the birth of her child some months before, and meanwhile she had had a severe attack of influenza. She was greatly reduced in strength and flesh. The symptoms and physical signs before described as belonging to abscess of the lung were present. The odor was the most offensive I ever encountered. The lesion was in the lower left lobe and the diagnosis was gangrenous abscess of the lung.

Case 2.—The other case is that of Mr. M., of St. Louis, the well known business man, of middle age, prominent in athletic circles. I was called in consultation with his attending physicians, Drs. Kuhn and Ludeking, in October of this year. The lesion was evidently not of so long standing as in the former case, and there was no history of a predisposing cause. It was also in the lower left lobe. In addition to the usual symptoms of abscess, there was the phenomenon of marked tympanitis at the site of the lesion, which would be relieved by severe coughing and leave an area of dullness well marked. It was concluded that the tympanitis was the result of the accumulation of air in a partly filled cavity, where by there was distension until it was forced out by a violent contraction from coughing. There was the same kind of offensive odor, but not so great, and the same grayish-green expectoration. The diagnosis again was abscess of the lung with gangrene. In each case the operation advised above was done and the diagnosis verified. The cavities were kept thoroughly washed out with a

weak carbolic acid solution and in each case complete recovery ensued. The fetid expectoration ceased, the temperature became less, and the patients began to improve immediately after the evacuation of the pus.

These cases will be more fully reported elsewhere from a surgical standpoint, but I have referred to them here to substantiate the position taken in this paper: 1. That abscess of the lung presents signs and symptoms which may admit of a positive diagnosis. 2. That abscess of the lung may be the result of, or complicate gangrene from occlusion of a bronchial artery. 3. That operation is often demanded, and that the safest operation is the excision of a rib, giving free opportunity to prevent accumulation in the pleural sac. 4. That the result of such operations indicate the value of this comparatively new field for surgical investigation.

2530 Locust street.

CYSTOMA OF THE ARYTENOID REGION OF THE LARYNX, WITH THE REPORT OF A CASE.

Read before the Section of Laryngology of the Tenth International Medical Congress, Berlin, 1890.

BY W. E. CASSELBERRY, M.D.,
OF CHICAGO.

PROFESSOR OF MATERIA MEDICA AND THERAPEUTICS, AND OF LARYNGOLOGY AND RHINOLOGY, IN THE CHICAGO MEDICAL COLLEGE; LARYNGOLOGIST TO THE WESLEY HOSPITAL, ETC.

Under this title it is proper to include only cysts, or neoplasms of predominating cystic formation, which originate from the immediate vicinity of one or other arytoid eminence, including the neighboring part of the inter-arytenoid fold and of the ary-epiglottic fold.

Recent literature has contained numerous reports of cystomata occurring elsewhere in the larynx. Schwartz, cited by Garel,¹ places the proportion of cysts among laryngeal neoplasms in general at 3 per cent., whilst Garel himself, out of a total of sixty cases, has met with cysts of the larynx sixteen times—an unusually large proportion of 25 per cent. Most of these were situated near the anterior third of the vocal cords, and not one was in the arytoid region. Massei,² of Naples, found among his 200 cases of laryngeal neoplasms thirteen cysts—6.5 per cent.

Cohen, in "Sajous' Annual" for 1889, cites five cases reported during the year: one of the epiglottis by Huijsman, three of the vocal cord, respectively by G. Hunter Mackenzie, Desvervigne Hayward and Seifert, and one of the ventricular band by Audubert. None of the arytoid region. Other cases of cyst of the vocal cord have

recently been reported by Major¹ and Fischer;² of cyst of the epiglottis by Photiades³ and Iarmuth;⁴ of the ventricular band by Hayward.⁵ Of cystoma of the arytenoid region we have been able to find recorded but a single case—that of Fundareno⁶ (*el Siglo Médico*, Madrid, April 21, 1889), although the monographs of Ulrich,⁷ Mourli⁸ and Cervisato,⁹ in the original, have been inaccessible to us. Another case, however, probably of the same nature, which was operated upon by Garel, is reported by Moncage¹⁰ under the name of "Fibrocytic Tumor of the Ary-epiglottic Fold."

The etiological factors in the development of cystoma in the arytenoid region do not differ from those of other laryngeal cysts, except that they seem capable of attaining a much larger size and of assuming more the character of a true neoplasm.

Pathological Histology.—Of cysts formed by the accumulation of substances within the cavities of preëxisting structures,¹¹ the first and most prominent division is that of "retention cysts," which includes, for example, simple cysts arising from obstruction in the tubules of the kidney, the ducts of the liver, the lacteal channels, sebaceous cysts and mucous cysts. Laryngeal cysts, when simple, have all presented the characteristics of "mucous retention cysts," and are formed by the retention of the secretions in some one or more of the glands of the mucous membrane. The duct of a mucous gland, perhaps at some period of acute inflammation of the larynx, becomes obstructed by epithelial debris or inflammatory swelling, and soon the exit is obliterated. This doubtless occurs with considerable frequency, like with the sebaceous glands of the skin, but in most instances, the glandular function being at the same time wholly suppressed, the affected structure subsequently undergoes desiccation or exfoliation, or, if the function is maintained, the old orifice may be reopened or a new one forced, either by mere pressure or through the process of supuration. In rarer instances, however, the accident of obstruction having happened, apparently, to a more vigorous gland, its secretion continues, is retained by a less yielding wall which is thereby distended to form a thin sac—a small and simple cyst, which is still devoid of any considerable formation of neoplastic matter. A case of this sort, situated on the ary epiglottic fold, we observed in 1882, under Prof. Chiari, at Prof. Schrötter's clinic, and we well remember the genial but emphatic phrase with which Chiari corrected a mistaken diagnosis—"Nein, Meine Herren, das ist eine Cyste."

Such a simple cyst of limited growth may remain quiescent, perhaps unnoticed, if favorably situated, for an indefinite period of time, or it may suddenly rupture and disappear. But otherwise, with certain individuals, eventually or at once, its presence excites an increased blood supply to the spot, which is utilized by perverted nature for a further production of endothelium, epithelium and intermediate connective tissue, forming a thick, fibrous wall sufficiently strong to resist the pressure of the constantly augmenting secretory contents. There is not now longer a mere distension of the structures of a preëxisting cavity, and its contents proceed not alone from the original gland formation, but its wall has a vascular supply and a growth of its own, the contents being elaborated by the entire lining membrane, which is apparently a product of the evolution of the original gland cells. Indeed, the transformation is into a veritable neoplasm which may very properly be dignified by the term cystoma.

Desvernine's¹² case having died of other causes, he reported the pathological histology of the "cystoma of the vocal cord" as follows: "It was found to be a retention cyst of glandular origin, due to inflammation beginning in the epithelium of the gland and progressing excentrically to the para-glandular connective tissue, which has become condensed layer by layer, with a highly fused fibrous envelope." The cavity of this cystoma measured only 5 millimetres transversely, and compared with our immense cystoma of the arytenoid region presently to be described, it was minute, but showed nevertheless, in its wall, evidence of independent growth.

We have tabulated and appended the records of four cases, including two of our own, one of which, presenting noteworthy features, we will relate in detail:

Mrs. F. P., æt. 25 years, referred by Dr. N. S. Davis, Jr., July 13, 1888, relates that she has had a noticeable habit since childhood of throwing her head forward when swallowing as if a slight impediment to deglutition existed. No other symptoms referable to the throat were noticed until May 30, 1888, "Decoration Day," when a "cold" from exposure, culminated at once in a severe attack of acute pharyngitis and laryngitis. Her voice became husky, and the hoarseness continued to increase until, at the end of two weeks, she was completely aphonic. Deglutition, which was at first unimpaired, except as indicated solely by the habit above mentioned, gradually became more and more difficult until, in less than a month, swallowing was restricted to fluids. A sense of discomfort from the "fulness" in her throat, but no real pain, was complained of.

Status Præsens.—Emaciation and debility are pronounced. Respiration is labored, and lividity

of the lips and other signs of impaired oxygenation of the blood are present. Laryngoscopic examination discloses an immense tumor, fully 4 centimetres in diameter, which occupies the entire top of the larynx, encroaches upon the œsophageal orifice and forces the epiglottis forward upon the tongue, nearly burying it from sight. (Fig. 1.)

FIG. 1.—Cystoma of the Larynx.

The vocal cords are hidden from view, but by drawing the tumor upwards and to the left, a glimpse of a part of the right vocal cord and the right arytenoid eminence is obtainable. The tumor is globular in shape, of fibrous appearance, hard and dense to the touch, but suggestive here and there of cystic contents, and presented on its surface ramifying vessels of considerable size.

The paroxysms of dyspnoea occasioned by the examination were so severe that one hesitated to undertake any sort of operative treatment, even for diagnostic purposes, without preliminary tracheotomy, which was therefore performed on July 22, 1888. Present, assisting, were Dr. W. W. Jaggard, Dr. F. S. Johnson, and Dr. McCullom. Ether anesthesia was employed, and herein lies a grave point of danger in such cases. A respiratory passage had been maintained, doubtless by aid of the throat muscles, serving to keep the neoplasm partly aside. With the earliest suspension of muscular action by the ether, the pharyngeal muscles collapsed upon the tumor and caused the latter to act as a complete stopper to the larynx, whereupon respiration ceased and the face blackened. In this condition of complete asphyxia the trachea was hastily opened, the tube inserted, and the patient then resuscitated by artificial respiration.

After a few days I punctured the neoplasm by means of a large curved needle attached to a hypodermic syringe, and withdrew about 8 ccm. of a light olive-colored, viscid fluid, which was sufficiently albuminous to completely solidify by boiling, and which showed under the microscope innumerable leucocytes. By the following day the tumor had regained nearly its original size through reaccumulation of the contents. A free opening was now made which permitted the es-

cape of fluid, and also of shreddy material too thick to flow through the needle. The collapsed wall was then drawn forcibly upward by a curved vulsellum, when it could be seen to be attached by a rather broad base over the whole of the left arytenoid eminence, including the adjoining end of the ventricular band and parts of the interarytenoid and ary-epiglottic folds. It was separated from its attachments and removed in several pieces by the use of a curved galvano-cautery snare, or galvano-cautery knife electrode, and long angular scissors.

The wall of the cyst varied from 1 to 3 millimetres in thickness and exhibited a rather fibrous aspect. Fragments of it were submitted for microscopic examination to Dr. Frank S. Johnson, Professor of Pathology in the Chicago Medical College, who reported the neoplasm, from the presence in spots of closely aggregated, small, round cells, to be probably sarcomatous—a cystic sarcoma. This opinion, somewhat doubtfully expressed at the time, is rendered still more doubtful by the subsequent favorable history of the case, and from a recent reinspection of the slides, jointly, by Dr. Johnson and myself, he submits the following report, with which I concur:

The tissue is cellular and quite vascular. The stroma is chiefly fibrous and is dotted with small, round and slightly angular cells, which in certain areas are very thickly aggregated and present the appearance somewhat of sarcoma, but they constitute, doubtless, only a young connective tissue. A few pavement-like cells on the edge of the section may possibly represent an endothelium.

In view of the possible sarcomatous nature of the cystoma the question of partial resection of the larynx was now considered, but after due consideration, the patient expressed herself as unwilling to submit to the operation without assurance of absolute necessity greater than we could give.

The larynx was not located deeply in the throat, and it seemed possible to destroy the remaining shreds of the growth and the whole seat of attachment by operating through the mouth with vulsellum forceps, scissors and galvano-cautery. This was the method adopted, but it required repeated operations, at intervals of two to three weeks, to thoroughly accomplish the result, for, notwithstanding the use of cocaine in spray and solution gradually advanced to the strength of 30 per cent., after the first two or three cauterizations or clippings, hæmorrhage and gagging interfered with further laryngoscopic observation.

The cartilages of Wisberg and of Santorini were removed, and the upper neighboring parts of the ary-epiglottic fold, interarytenoid fold, and ventricular band were destroyed. The arytenoid cartilage remains, but it is partially ankylosed, which impairs somewhat the mobility of the left vocal cord. The cords are otherwise intact and the voice is very good. (Fig. 2.)

Two years have passed, and there is no sign of

recurrence. The tracheotomy tube, having been worn corked up for a time, was withdrawn at the end of a year. Healing of the opening was facilitated by occasional freshening of the edges by the cauterizer. It is now perfectly closed.

Annotations in Retrospect.—Certain queries arise concerning the treatment adopted, and first, Was tracheotomy necessary? Fundareno's¹⁵ case terminated successfully without it. "A soft tumor of the size and shape of a walnut blocked up the posterior half of the laryngeal cavity. An incision was made into the cyst with the laryngeal knife of Bruns, when a clear fluid mixed with granular and fatty matter escaped. Then it was seen to be attached over the right arytenoid cartilage. The cystic membrane was removed and the place of attachment cauterized with chromic acid."

FIG. 2.—After operation.

Should an anæsthetic have been administered? Death therefrom was certainly averted only by prompt albeit deliberate action. But the American surgeon does not contemplate with equanimity the operation of tracheotomy without anæsthesia. No little surprise was occasioned by the discussion which recently waged in France relating to tracheotomy with or without an anæsthetic in cases of membranous croup, in which condition, in America, it is always administered, notwithstanding dyspnoea, unless the patient is already moribund.

But these are not wholly analogous cases, and another time, with a tumor similarly situated, requiring quasi-voluntary muscular action to maintain patency of the respiratory passages, I would make the tracheotomy with only local anæsthesia by ether spray to the skin and cocaine spray to deeper layers as reached, aided perhaps by hypodermics of cocaine.

Concerning the duration of development of the cystoma, it seems more reasonable to assume that a small cyst, quiescent, or of very slow growth, had existed for years, as indicated by the slight disability in deglutition, and that this was stimulated to active growth by the acute inflammation of the surrounding parts contracted on "Decoration Day," rather than to suppose that the

TABLE OF CASES OF CYST OF THE ARYENOID REGION OF THE LARYNX.

No. Date.	Operator or Reference.	Sex.	Age.	Previous Duration of Symptoms.	Situation and Extent.	Points of Attachment.	Pathological Nature.	Treatment.	Result.
1882	Chiari and Casselberry, Schröter's Vienna Clinic, Sec. in Larynx, Tenth Int'l Congress.	Male.	30	None	Right ary-epiglottic fold near the arytenoid, size of small split pea	Same	Simple retention cyst	None	None
1889	Monagré and Garel, "Internat. Centralb. f. Larynx, Rhinol.," etc., l. vi, S. 608.	Ary-epiglottic fold.	Same	Fibro-cystic tumor	Removal by galvano-caut. snare	Presumably cured.
1889	Fundareno, Segio Medico, Apr. 21, Jour. of Larynx and Rhinol., Vol. iii, 1889.	Male.	30	...	Right arytenoid region, size of a walnut, covering two-thirds of larynx.	Mucous membrane over right arytenoid.	Cyst	Evacuated, cystic membrane removed, base cauterized with chromic acid	Presumably cured.
1890	Casselberry, Tenth Int'l Med. Congress, Sec. in Laryngology, Berlin, 1890.	Female.	30	Six weeks.	Left arytenoid region, size of large black walnut, covered all but anterior angle of glottis, seriously impaired deglutition and respiration.	Mucous and sub-mucous tissues over left arytenoid region, ary-epiglottic fold & ventricular band.	Cystoma	Evacuated, removed by snare, well after dissection and basipharyngeal cauterization of base by galvanocautery.	Cured, remains well after 2 1/2 years.

In our own case the tumor was larger, firmer, the diagnosis at first uncertain, whilst the dyspnoea demanded immediate relief and rendered hazardous any attempt at operating *per vias naturales* without an independent artificial opening for respiration. And subsequently, by reason of the ready induction of spasm of the glottis, it would have been quite impossible, without tracheotomy, to have effected that thorough destruction of the seat of attachment, so desirable on account of the possible sarcomatous nature of the neoplasm.

neoplasm had been wholly formed in the short period of six weeks, which intervened between the eventful "Decoration Day" and the time of our first examination.

The suspicion first entertained of a sarcomatous element in the case, we believe to have been reasonably excluded by the subsequent course of events, and that we had to deal merely with an immense cystoma which originated in a simple mucous retention cyst. An analytical record of cases is given.

¹⁵ Loc. cit.

MEDICO-LEGAL NOTES.

BY HENRY A. RILEY, ESQ.,
OF NEW YORK.

HYPNOTISM.

The subject of hypnotism continues to attract great attention, both in the public journals and at the meetings of learned societies. At a recent meeting of the Medico-Legal Society of New York a committee made a preliminary report, and this was, at a later meeting, discussed by the members.

Dr. E. P. Thwing said: The trance sleep is not a disease, although neurotic conditions predispose to it. Nor does sensitiveness to hypnotic influence imply small brain power. Hypnotism is not necessarily productive of harm, and in many cases in medical practice has proved valuable.

There was a decided difference of opinion as to the value and propriety of public exhibitions of hypnotism. Several such exhibitions have been given in this city, some of which have attracted attention from physicians as well as from the curious and investigating public.

Dr. Paul Gibier, the well-known head of the Pasteur Institute, approved of public exhibitions in so far as they served to bring to light new truths of interest to science. It will be of interest to recall the fact that the city authorities of Cincinnati, at the suggestion of Dr. Prendergast, the Health Officer, have prohibited all public exhibitions in that city.

TAKING AWAY THE CHARTER OF A MEDICAL COLLEGE.

A bill is now pending in the New Jersey Legislature to annul the charter of the Medical and Surgical College of the State of New Jersey. The measure has already passed the Senate, and has been favorably reported in the house. It was introduced at the request of the Hudson County Medical Society, which recently adopted resolutions to the effect that "several members of the faculty are either incompetent to deliver lectures on the subjects assigned them, or are graduates of disreputable or fraudulent medical colleges; that the facilities for instruction are inadequate; that the requirements of the charter of the College are far below the minimum requirements of medical colleges adopted and demanded by all the medical authorities at the present time."

The State Board of Medical Examiners is urging the passage of the bill.

STATE REGULATION OF VICE.

The New York Committee for the Prevention of State Regulation of Vice met recently and adopted a protest against the passage of a bill, pending in the New York Legislature, to lower the age of consent on the part of young girls to their own ruin from sixteen to thirteen years.

The committee also passed a resolution in favor of the appointment of women matrons at the police station houses in New York City.

It is pleasant to state that in all probability both of these recommendations will be effective, and that the Legislature will hardly dare to lower the age of consent, while there seems to be no special opposition to the police matron law.

CREMATION AND THE LAW.

In England very recently three prominent men have been cremated—Baron Huddleston, Mr. Charles Kinglake, and the Duke of Bedford—and some of the papers are discussing the legality of this method of disposing of the dead. The decisions seem, however, to have settled the point. In a very elaborate decision some few years ago, by Justice Stephen, it was held that it was not a misdemeanor to burn a body unless it was so done as to create a public nuisance, or done in order to prevent the coroner holding an inquest on the body.

In this country there has never been any serious discussion of the question in the courts, as the legality of cremation seems to have been conceded. It does not appear, however, that the custom of burning the dead is becoming very much observed.

PRACTICING WITHOUT A DIPLOMA.

The New York County Medical Society frequently brings into court persons practicing medicine who have no legal right to do so, not having diplomas; and the convictions are quite numerous. In a recent case the offender had been before the court once before, but claimed that his lawyer had given him a paper which purported to be a decision reversing the former conviction. The lawyer was a shyster, who is now serving a term in the State Prison for forging a divorce decree. The Judge said that it was simply a case of a medical shark falling into the hands of two legal sharks, and sentenced the bogus doctor to imprisonment for 100 days in the penitentiary, together with a fine of \$100.

BOARDS OF HEALTH MUST PAY FOR MISTAKES.

In Massachusetts it was recently decided that the law permitted Boards of Health to kill horses infected with the glanders, but that it did not free them from liability if they killed animals which did not, in fact, have the disease. In such a case they would be liable in damages.

INFECTED MEAT IN NEW YORK.

The amount of bad meat, fish and vegetables seized each year in New York City by the officials of the Board of Health, would surprise almost every reader. According to the report just prepared there was confiscated 1,200,000 pounds of tainted meat and fish, and 1,056,000 pounds of bad fruit and vegetables. The milk inspectors

examined 97,000 samples of milk, and caused 299 arrests for milk adulteration. Milk was found for sale in over 6,000 stores in the city.

HOW TO RUN A SLAUGHTER-HOUSE.

The following is the direction given in a Michigan suit for the proper management of a slaughter-house: "Complainants are entitled to a decree requiring defendant to remove from his premises every day all manure, blood, offal, hair and other refuse of his establishment, in covered garbage wagons, such as are in use by the Board of Public Works in the city of Detroit, or in other wagons that will effectively avoid the spread of offensive odors; to thoroughly clean, cleanse and disinfect his premises daily; to provide sufficient pens for the hogs in store so that they shall not be crowded and rendered noisy and quarrelsome by discomfort while in confinement, and to use such other precautions as are necessary to render his place of business clean and wholesome."

MEDICAL PROGRESS.

Therapeutics and Pharmacology.

TREATMENT OF TYPHOID FEVER WITH CHLOROFORM.—DR. STEPP, of Nürnberg, contributes to the *Münchener Med. Wochenschr.* an account of the excellent results he has obtained in the treatment of typhoid fever with chloroform. The drug is given in 5 minim doses thrice daily. He claims for the medication a direct and favorable influence upon the course of the disease; the tongue becomes moist, somnolence and delirium disappear, and immediate improvement is noted in the general condition. The temperature is usually lessened in from eight to ten days, relapses occasionally occurred, and he notes the death of one patient. The fever stage averaged, in severe cases, nineteen days; in lighter forms, eight days.

The writer thinks that the chloroform is absorbed directly into the blood, where it exerts a specific anti-bacterial effect. He has never observed unpleasant consequences resulting from the medication.

PILOCARPIN IN CHRONIC RHEUMATISM.—DR. HOCHHOLT, physician to the Pest Hospital *Semaine Médical*, July 2, 1890, reports excellent results in chronic rheumatism, accompanied by effusion into the joints and some thickening, with pilocarpin. Coleman Korda, a confrère of his, had observed similar good results ten years before. Korda attributed the favorable action of the drug to its power of increasing tissue change, aiding elimination and thus favoring the absorption of inflammatory exudates. It is to this property that the drug owes its value in ophthalmol-

ogy and otology. Pilocarpin is of added value from the fact that we have no remedies useful in the chronic joint affections of rheumatism, the ordinary drugs, salicylates, antipyrin, etc., being useless in these conditions.

Physiology.

THE PENIS PERCUSSION REFLEX.—We learn with each year a few additional objective signs of disease, and with these come increased precision in diagnosis. It is but a few years since the significance of absence or variation of the patellar tendon reflex has been understood, though the phenomenon of contraction of the thigh muscles when the tendon was struck, must have been known to the school boys of ancient Rome. Since the diagnostic value of alterations of this reflex have been learned, many others have been found and studied. The last is announced by DR. C. H. HUGHES, *Alienist and Neurologist*, January, 1891, under the term "virile reflex," because if it is impaired or lost, in a person with a healthy spinal cord, it indicates a loss or abeyance of the sexual function. The reflex is produced by grasping the penis by the foreskin, between the index finger and thumb, and pulling the organ firmly toward the umbilicus, at the same time allowing the ring and little fingers of the same hand to rest upon the dorsum of the organ. If, while in this condition, the organ is struck sharply a distinct retraction of the bulbo-cavernosus portion will be felt. Dr. Hughes says that it is often, but by no means always, found in sympathy with the other reflexes of the lumbo-dorsal spine. He has found it absent in old men who have acknowledged complete virile incapacity, and also lessened in neurasthenia and masturbation.

If it shall appear upon further investigation that the claims made by Dr. Hughes are correct, we certainly have a valuable diagnostic sign in a considerable number of medico-legal cases. It is a common thing for men, especially those advanced in years, if accused of sexual crimes, to plead total impotency. So far as the examination of the medical jurist is concerned, he can only report as to the conformation of the organs. The virile power is beyond his investigation. Then, too, it ought to prove of differential diagnostic value in forms of psychological impotency. We sincerely hope that the sign may prove to be true, as it will then prevent the somewhat unfortunate *contemps* of a man being convicted of bastardy, and his wife obtaining a divorce on the ground of impotency, at the same term of court.

RESULTS OF SECTION OF THE CORPUS CALLOSUM.—KORANYI, *Präger's Arch.*, xlvii, p. 35, in Golz's laboratory in Strasburg, has divided the corpus callosum in a number of dogs, and finds that, provided other parts of the brain be not injured, especially the cerebral hemispheres, there

are no symptoms whatever resulting from the lesion. Both halves of the body appear to retain their normal motor and sensory functions, and appear to act in unison together.

Obstetrics and Diseases of Women.

DANGER OF VAGINAL INJECTIONS.—DR. ROULIN (*Journal de Médecine de Paris*, December 14, 1890), describes three cases where women suffered from severe symptoms after the use of vaginal injections, administered by themselves when in a sitting position. The first used the douche can, fixing it rather high on the wall. Immediately after the injection violent hypogastric and lumbar pains set in, followed by vertigo and vomiting. The abdomen was not sensitive on pressure, though pain was intense. Metrorrhagia followed and lasted for two or three days, but the pain ceased in twenty-four hours. The second case was almost precisely similar, excepting that the patient had used a hand syringe, and the symptoms were less severe. The third case also used a hand syringe. She felt a pain like a blow across the belly, but continued the injection; when it was ended lumbar and abdominal pains came on severely, with rigors and chattering of the teeth, but no vomiting. The symptoms recurred on the next day when the patient got up, but on the third day she felt well and free from pain. Dr. Roulin employs laudanum enemata for these cases. The cause of the pain is obscure. The fluid rushing into the uterine cavity may act as a foreign body and set up conditions sometimes provoked by catheterism. The admission of air into the uterine sinuses has been, according to Depaul, the cause of sudden death during douching of the cervix to produce abortion. Dr. Roulin believes that water may have entered in his cases. He insists that patients must be taught how to administer vaginal injections to themselves. The patient must lie on her back and only introduce the nozzle for a short distance; nor must she play too strong a jet of fluid into the vagina.—*British Medical Journal*.

Bacteriology.

VIRULENCE OF TUBERCLE BACILLUS.—PROFESSOR A. MAFFUCCI, in a preliminary communication (*Centralbl. für allgemeine Pathologie u. pathologische Anatomie*, Band i, No. 26, December 15, 1890) concludes that all Hammerschlag's experiments with the alcoholic extracts of pure cultivations of tubercle bacillus cannot, in face of the clinical nature of tuberculous disease in the human subject, be looked upon as conclusive. There is, however, he considers, some poison developed by the tubercle bacillus, especially in older growths, which by its action produces marasmus, apparently by interfering with the nutrition of the cellular elements of the body. What relation the bacilli and their products bear to inflammation, fever, marasmus and degeneration,

he is not prepared to state; but the experiments that he has recently made confirm those that he published in 1879, in which he found that the tubercle bacillus from a mammalian, when injected into a laying fowl, caused the embryos from the eggs to die with all the characteristic features of a marasmus. He has observed the same thing in the hens themselves when they have been inoculated with "perlsucht," and even with active cultivations of the tubercle bacillus from mammalian animals; whilst, from clinical observation, he is also of opinion that the caseous masses in tuberculous individuals are the exciting cause of the marasmus that is so frequently met with in patients affected with tuberculous glands, bones or joints, and in cases of tuberculous phthisis. He has now carried on a series of experiments on guinea pigs with pure cultivations of tubercle bacillus (from mammalian animals) which had been allowed to grow for one, two, three or six months on consolidated blood serum to which glycerine had been added, or on fluid blood serum alone. The culture was then sterilized at a temperature of 65° to 70° C., continued for one or two hours, or by intermittent sterilization. Cultures of more than six months' standing were found to be already sterile, and were therefore not specially treated. Any of these sterilized cultures introduced into guinea pigs induced, in from fourteen days to six months, marked wasting, but no tubercle bacilli could be found by histological examination or by cultivation. There was usually congestion of the lung and of the kidney, the splenic follicles were wasted, the pulp was also atrophied, but was usually somewhat congested, and considerable quantities of pigment might be observed in the pulp cells, and even lying free outside them. The atrophy, however, was almost invariably well marked, and the liver cells were usually considerably wasted. He concludes that this toxic substance is not destroyed in the body of an animal which dies from marasmus, and he holds that these observations must have a very important bearing on the ultimate success or failure of Koch's treatment.—*British Medical Journal*.

BACTERIA IN THE AIR.—PROF. ROSTER of the Istituto degli Studi Superiori, of Florence, has recently examined the air of the island of Elba, and comes to the following important and practical conclusions: 1. The air of an island, even when of considerable size, contains fewer bacteria than the mainland. 2. When the wind is off the sea the number of bacteria is enormously decreased. 3. A comparatively narrow arm of the sea is sufficient to purify the air blowing over it. 4. Atmospheric bacteria increase in proportion to the velocity of the wind. 5. Rain is the most important factor in purifying air of its contained germs.

JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No. 68 WARREN AVE.,
CHICAGO, ILLINOIS.

All members of the Association should send their Annual Dues to the Treasurer, Richard J. Duglison, M.D., Lock Box 1274, Philadelphia, Pa.

LONDON OFFICE, 57 AND 59 LUDGATE HILL.

SATURDAY, MARCH 7, 1891.

THE LESSON OF THE FILARIA SANGUINIS HOMINIS.

The greatest achievements of medicine in the past have been in clinical observation, those of the present are in biological investigation. The uncertain methods of the former are reinforced by the verdict of a jury of the profession at large; the positive decisions of the latter must be confirmed by the same method after they are handed down by the expert. No more brilliant study of parasitism is to be found in the annals of biology than that which this little hæmatozoan furnished.

DR. RUDOLPH MATAS in the January number of the *New Orleans Medical and Surgical Journal*, cites a case of parasitic chylocele, which illustrates the rational treatment of this disease, following a positive diagnosis and relative indications dependant on an exact knowledge of the life history of the filaria. This article is a model of medical literature, and it should be carefully studied by every physician on the Gulf coast. It is another witness to the richness of the New Orleans clinic in tropical and sub-tropical diseases, and promises for that city an opportunity for medical study and clinical investigation of these diseases, without the dangers which attend a residence in the tropics.

The relation of the filaria to chyluria was first noticed by WACHERER in Bahia in 1866, but DEMARGUAY had found and described the same wormlike form in the chylous fluid from a hydrocele in 1863. This little worm, however, did not escape the penetrating eye of DR. J. H. SALISBURY, who, in 1868, named it "trichina

cystica." LEWIS, of Calcutta, first found the embryonic worm in the circulating blood, and the mature and living male and female in a piece of scrotum amputated for elephantiasis. The most interesting and brilliant chapter in the history of our little animal is associated with the name of PATRICK MANSON. It was long known that the embryonic and a sexual filaria lived equally well in the blood and lymph, and that their presence there depended upon a mature and sexual female of comparatively prodigious size confined in some lymph space, usually in the scrotum. None of the myriads of embryos ever became sexual while in the original host. The sexual liberator was supposed to lie in some intermediary host. It remained for BANCROFT, of Australia, to suggest (1877), and MANSON, of China, to prove (1881), that the mosquito is the sexual liberator of the filaria sanguinis hominis.

The adult sexual filaria has never been found outside the lymph glands or lymph sacs. There the female is coiled up and her uteri and vagina are crowded with embryos in various stages of development. During the night the free embryos are found in enormous numbers in the blood of the patient; but during the day the blood is free from them, as MANSON first proved. This periodicity points to a remarkable adaptation when we learn that the nocturnal mosquito dips her proboscis into the circulating blood and fills her stomach with a drop of blood containing sometimes one hundred and twenty embryo filarie. Some of these are carried, directly or indirectly, to a second host to become sexually mature worms, and give rise to all the symptoms of invasion with the embryos. We can not recount all the interesting and astonishing features of this rare parasite. It may be compared with the filaria of the dog, which does become sexually mature in the primary host, and with the plasmodium malarie, which shows a parallel periodicity.

In the United States, the appearance of the filaria has been studied by three careful investigators, GUITERAS,¹ MARTIN,² and DR. SAUSURE,³ and although the climate of Southern United States is barely subtropical, a very astonishing number of native cases have been presented, mostly from Charleston. The pathology and clinical history of the chylocele of the tunica

¹ Medical News, April, 1886.² Annals of Surgery, 1888.³ Medical News, 1890.

vaginalis testis has been first fully demonstrated by MASTIN, and we are proud to say his demonstration has borne fruit in the successful treatment of a case by DR. MATAS, to whom we are indebted for the opportunity of calling attention to this subject again. We predict that imported cases will be found in the Northern States, and trust that every case of chyluria, chylocele, elephantiasis, suppurating multiple lymphadenitis, chylo-thorax and chylous ascites will receive careful clinical examination for this parasite.

This is a typical obligate parasite and, as might be predicted, it is not destructive to its host. Patients live for many years under proper conditions, and their chief source of danger is from infection with more destructive parasites, such as the erysipelas coccus and the pyogenic bacteria. Recovery from the uncomplicated disease is the rule when the patient emigrates to a cold climate, or, otherwise, when the parent worm is removed by operation or dies from natural or accidental causes. The prognosis without emigration depends largely on the number of sexual females in the host and the risk of wound diseases.

The remarkable effect of a cold climate on this parasite, resulting in the death of the pregnant female and consequent disappearance of the disease, furnishes an analogy which should be remembered, not only in its narrow application to malaria, but to all parasitic diseases. For, however uniform the conditions of human vitality seem to us to be at all times and in all places, we have indubitable evidence here of such vital changes as result in the death of an otherwise permanent parasite. In these times of vigorous therapy, let not so important a suggestion go unnoticed, but let it furnish a theme for meditation, for hypothesis, for investigation, and for scientific deduction.

FUNERAL REFORM. DANGERS OF DECORATION DAY.

The *Lancet* inveighs against the practice of so conducting funerals as to endanger human lives. The past winter has been unusually chilly and cold in England, and the editor of the *Lancet* has had occasion to notice not a few distressful consequences due to the standing of participants at funeral exercises with their heads bared. In fine weather this mark of respect may very well be

observed, but in the winter time it is too liable to be attended with grave risks to be looked upon with favor by medical men. The editor commends the shortening of the out-door services in cold and stormy weather, as has been voluntarily undertaken by some of the clergy, and the keeping of the hat on the head except for a moment or more at a time when the word "Amen" after prayer, or some like passage, is pronounced by the clergyman. Standing with the head bared is indeed a seemly token of respect to the dead, but a due regard for the living teaches us that a reform in this particular may properly be expected before this century closes. The dangers of Decoration Day deserve consideration here. We hold that it is unfortunate that that holiday has been located so early in the year, while yet the soil of our cemeteries is saturated with damp and unoxidized deposits of a winter's harvest of snow and frost, and mould and vegetable decay. We have seen too many instances of injury to health and of death even, caused by that kind of filiality and loyalty which leads the families of departed patriots and others to decorate the last resting-places of their loved ones, to be admirers of the practice from the standpoint of health preservation. This act of respect has, in not a few instances, been the occasion of a second visit, soon after, to the cemetery, for the purpose of closing up a newly made grave due to Decoration Day exposures.

VENESECTION.

It is quite a noteworthy coincidence that the subject of venesection has been the theme of extended and favorable comment, within the past fortnight or so, in London, Edinburgh, and in this country. Were it not for the very evident modification of the remarks put forth the critic of to-day would fain be tempted to regard the flight of the past half century as a dream—that the heroic times of blood-letting were but as yesterday. And yet progress in medicine is but an awakening—after a variable lapse of time—to a due appreciation and proper regard of means. If, in a particular measure, it requires fifty years of slumber or ostracism to insure in it that which is truly good and for the public weal, we had best view it through our optimistic glasses, and complacently await the advent of the next *time-tried* expedient. Experience teaches us—and very

plainly in this case of venesection—that it is useless to look for any *one* means by which to combat the whole diversified army of disease. This has been clearly illustrated by history, notably of the last one hundred years. Enthusiasm—professional enthusiasm—in the direction of meteoric medicine, if we may be allowed the expression, is commendable to a degree, but yet is inevitably disastrous. This was certainly the result with venesection. It was relegated to such oblivion that the student of medicine during the past two decades at least, has scarce heard it mentioned, and never observed its use. And so it has been—with few exceptions—throughout the entire field of medical research. History repeats itself almost daily upon this point.

When DR. PYE-SMITH read his paper, entitled: "The Therapeutical Value of Venesection: its Indications and its Limits," before the Royal Medical and Chirurgical Society, it is interesting to note how conservative, not only the title and contents of DR. PYE-SMITH's contribution, but its reception by the Society and the discussion which followed the paper. Some of the foremost medical men of England came forward with their opinions—well-washed by the ever-lapping waves of Time—and humbly laid them down at the feet of Record. O Shades of fifty years ago! O Whilom Hero of the Lance, pray heed e'en this faint justification! Continently hides her scrawny lines and a newer light—and brighter—bids fair to shine!

Physicians and Surgeons alike, at this meeting, expressed themselves in favor of venesection in those cases wherein depletion was clearly indicated, viz., and more particularly, first, in cyanosis with distention of the right side of the heart, whether from pulmonary or some other obstacle to the circulation; secondly, the intense pain of aortic aneurism; and thirdly, uræmic and prolonged epileptic convulsions.

DR. PYE-SMITH justifies himself fully—which the discussion bears out—by the statement that he felt the time had come when it could be shown that, if rightly used, venesection was a valuable remedy.

ANOTHER DEATH FROM CHLOROFORM.

Another death under chloroform recently occurred at Indianapolis. A physician, without professional assistance, exhibited the anæsthetic

to a patient previous to the opening of a mammary abscess. Death came quickly, and before the operation was commenced.

The *Indiana Medical Journal* editorially criticises the case, with the following conclusions:

1. That the administration of an anæsthetic by a physician for any purpose whatever, except in obstetrics and cases of emergency, without the presence of another physician, when such can be procured, is to be condemned.
2. In a large city like Indianapolis, where the services of an expert in anæsthesia can always be procured, the physician who does not avail himself of such services should be held to a strict accountability for any disastrous results that may occur.
3. The administration of a general anæsthetic, for the purpose of opening a mammary abscess, is wholly unjustifiable.
4. In view of the above unassailable propositions, the death of the above patient should not be attributed to an unavoidable accident, from the necessary and skilful administration of chloroform.

A LESSON IN LONGEVITY.

The *Medical Age* draws a lesson in longevity from the life of the late GEORGE BANCROFT, in which while it admits that there is no system of living which will insure longevity, yet, withal, there are certain considerations tending that way, and which, if carefully lived up to, offers probably the best chance of reaching close to, if not quite, the hundred year period. The following pertinent advice is given:

Live as much as possible out of doors, never letting a day pass without spending at least three or four hours in the open air.

Keep all the powers of mind and body occupied in congenial work. The muscles should be developed and the mind kept active.

Avoid excesses of all kinds, whether of food, drink, or of whatever nature they may be. Be moderate in all things.

Never despair. Be cheerful at all times. Never give way to anger. Never let the trials of one day pass over to the next.

The period from fifty to seventy-five years should not be passed in idleness, or abandonment of all work. Here is where a great many men fail—they resign all care or interest in worldly affairs, and rest of body and mind begins. They throw up their business and retire to private life, which in too many cases proves to be a suicidal policy.

During the next period—the period from seventy-five years to one hundred years, while the powers of life are at their lowest ebb, one cannot be too careful about "catching cold." Bronchitis is a most prolific cause of death in the aged. During this last period rest should be in abundance.

EDITORIAL NOTES.

RAILROAD TICKET ARRANGEMENTS FOR THE ANNUAL MEETING.—The Railroad Associations have agreed to sell tickets on the certificate plan, as last year, for one full fare going, one-third fare returning. *All must obtain a certificate on purchasing ticket to Washington, OR THEY CAN NOT HAVE THE REDUCTION IN RETURNING.*

AMERICAN MEDICAL COLLEGE ASSOCIATION.—The next meeting of the American Medical College Association will convene at the Arlington Hotel, Washington, D. C., at 8 o'clock P.M., May 4, 1891. The indications point to a very interesting session and a representation from a large majority of the Colleges of the United States. The special committee on permanent organization is at work, and will be ready to report at this meeting.

A GOOD RECORD.—The report of the Medical Department of Harvard College gives the total number of students enrolled during the year 1889-'90 as 304; and of these 156 had literary or scientific degrees—an excellent record in a very commendable direction. The force of a higher teaching and of sterner requirements is also shown by the fact that out of seventy-five applicants for the degree of Doctor of Medicine in the three-years' course, twenty-two were rejected; while out of fifteen applicants for the same degree in the four-years' course, two were rejected, and four received the degree *cum laude*. There is food for thought, as well as a decided plea, in these figures.

SOCIAL EVIL ACT.—The Legislature of Missouri has listened to the second reading of an Act for the regulation of prostitution. The fundamental points of the bill are patterned after the German laws, which have proved to be ineffective.

LEPROSY IN MINNESOTA.—The State Board of Health of Minnesota report sixteen cases of leprosy within its jurisdiction. It is quite entirely among emigrants.

AIDS TO MILITARY FIELD SERVICE.—The French have adopted a very simple yet serviceable plan of supplying each soldier with a packet of surgical dressings suitable for immediate use, and always present. The packet consists of antiseptic gauze, absorbent cotton, and bandage, together with two safety pins. All this is folded com-

pactly, surrounded by oiled silk, stitched within another covering of durable material, which renders it waterproof, and sewed upon the inside of the clothing over the left breast.

NEW COLLEGE BUILDING.—Plans are out, furnished by S. S. Beman, architect, for a new four story building for the Chicago Medical College. It is to cost one hundred thousand dollars, and is to be located on Dearborn St., near Twenty-fourth.

COLLEGE SOCIETIES.—That medicine is gradually acquiring that recognition to which its nobleness and scientific character entitles it, is indicated—to a degree—by the establishment and progress of fraternal, Greek-letter chapters at the larger and more progressive centres of medical learning. The *Nu Sigma Nu* confraternity (Medical) held its ninth annual meeting at Detroit recently, there being a representation from chapters located at Ann Arbor, Detroit, Pittsburg, Philadelphia, and Minneapolis.

HARVARD ALUMNI IN NEW YORK CITY.—The graduates of the Medical department of Harvard, now residing in New York City, have of late organized into an association. Monthly meetings will be held.

PRACTICAL LECTURES IN PRACTICAL FIELDS.—A free course of practical lectures is announced for mothers and nurses, at the New York Post-Graduate Medical School. Among the subjects to be treated are the following: "The Care of the Eye;" "The Most Frequent Surgical Incidents in Infancy and Early Childhood;" "The Care of the Skin in Health and Disease;" "Practical Points in the Nursing at the Babies' Wards as Employed in Lung Diseases, Fevers, Intestinal Diseases, etc.;" and "Infant Feeding and the General Care of Young Children."

THE WAY THEY DO AT VIENNA.—Late correspondence to the *Medical Record* rehearses the details of a sudden death upon the operating table—from the occurrence of an air-thrombus, as was shown by the autopsy—and following the operation for the removal of a goitre. It was at Billroth's public clinic, and the absence of measures which aid resuscitation was notable, however impossible of success their application might have been. Yet it was the events following, more than the "shadows before," which are

unique, as will be illustrated by the following quotation: "A most unpleasant impression was made on all the foreigners present by this tragic spectacle, and one could not but be struck by the unshaken coolness with which the surgeon, after the dead body of his patient had been carried out, proceeded immediately to perform a goitre extirpation on a second case—this time with a happier result."

MEDICAL LEGISLATION.—A bill to regulate the practice of medicine in California has been introduced before the legislative assembly at present in session. The bill provides for the establishment of a State Board of Medical Examiners consisting of seven members, appointed by the Governor, one from each of the well-established medical schools, and the others at large.

BROMOFORM, which has recently received wider endorsement in the treatment of whooping cough, was first brought forward as a remedy in this disease by Dr. Stepp, of Nürnberg, in 1889, who spoke of its value by both inhalation and internal administration. According to *Phar. Zeitsch. für Russland*, Stepp administered it in the following manner: bromoform 10 drops, alcohol 3 to 5 c.c., aqua dest. 100 c. c., syrupus 10 c. c. A cure is claimed in from five to ten days.

FOREIGN BODY IN THE MALE BLADDER.—Dr. Geo. H. Monks, of Boston, mentions in the *Boston Medical and Surgical Journal*, the removal by perineal section, of a piece of lead pencil over two inches long from the male bladder. The substance had been introduced by the patient with a view of overcoming a stricture of the urethra.

MEDICAL ITEMS.

MEDICAL LEGISLATION IN MISSOURI.—There is now pending in the Missouri legislature a bill to compel all medical colleges in the State to adopt three courses of lectures as a condition for graduation. All of the medical colleges in the State, excepting one, are favorable to the bill.

THE ILLINOIS STATE BOARD OF HEALTH has decided that hereafter it will recognize no foreign diploma that does not confer upon its holder the right to practice medicine in the country in which it was granted. The holder of an Austrian, a German, Russian, or Swiss diploma, wishing to practice in Illinois, must hereafter pass an examination

before the Board, unless he have a pass certificate from a government examining commission. The holder of a Canadian diploma, unless a licentiate of the College of Physicians and Surgeons of Ontario and Quebec, must pass an examination in order to be licensed in Illinois.

THE PREVENTION OF NARCOTIC INEBRIETY.—At a meeting of the American Association for the Cure of Inebriety, held February 18, at the Academy of Medicine, New York, Dr. J. B. Mattison, of Brooklyn, offered the following preamble and resolutions:

WHEREAS, a leading cause of morphinism, chloralism and cocaineism is the facility with which morphine, chloral and cocaine can be procured from pharmacists: and,

WHEREAS the refilling of prescriptions containing these drugs is a potent factor in the rise and growth of these diseases:

Therefore, be it resolved, as the sense of this Association, that no retail druggist should sell morphine, chloral or cocaine, except on a physician's prescription.

That no prescription containing morphine, chloral or cocaine should be refilled except on the written order of a physician.

These were unanimously adopted, and a committee consisting of Drs. Mattison, Crothers and Wright, was appointed to secure legislation along the line of the resolutions.

In future all candidates for medical degrees in France must produce a certificate of re-vaccination according to the regulations, otherwise they will be debarred from registration.

THE STATE BOARD OF HEALTH OF MAINE has introduced a bill into the legislature to provide for the registration of vital statistics. The bill was prepared by the State Board of Health after an extended examination of the existing laws of other States, and an effort is now being made to secure its passage. It seems almost needless to point out the value of such a bill. An official registration of births, marriages and deaths, in such a form as to make it furnish facts available and valuable for various purposes, is considered so important a work that most civilized States and nations have not omitted to provide for it. Vital statistics, when properly collected and recorded, are invaluable for a variety of purposes which will readily suggest themselves, and it is, therefore, somewhat remarkable that the State of Maine should have thus far neglected to provide for their registration.—*Sanitary News*.

TOPICS OF THE WEEK.

THE LONDON LANCET

For years this valuable journal has occupied a foremost position in the field of medical literature.

It has achieved a success of which any Briton may justly be proud, and we, as Americans, are none the less ready to accord to it the preëminence which by the herculean labors of its founder it finally came to command. The difficulties which it encountered were simply immense; but by reason of these its triumphs were the more conspicuous. Medical journalism has everywhere its obstacles—hindrances, criticisms and discouragements—and those who become familiar with the earlier history of *The Lancet* will discover that such besetments are by no means peculiar to medical journalism in America.

We are confident that American readers will be deeply interested in a brief recital of some of the earlier experiences of *The Lancet* as given recently by one of its correspondents, and we quote from his article as follows. He says:

I have recently had the curiosity to go through the files of *The Lancet* with the object of discovering and recording if possible the tone and aims of that journal from its inception, and the enormous labor has been amply repaid by the discovery of the rich mine of wealth which the volumes contain. I believe I have discovered the secret of the unparalleled success and the high reputation of the chief organ of the medical profession. In one of the volumes I came across what may be called *The Lancet's* confession of faith. "*The Lancet* will perpetuate the memory of Thomas Wakley—the founder of this journal—by cherishing after his death the principles to which he consecrated his life." The solemnity of expression in the passage on the occasion of the death of the founder led me to further inquire by what motives he had been actuated, what such a memory and example required of his successors, and how far the solemn promise had been fulfilled by them. What had he to gain in requiring that medical men should be adequately rewarded for their labors? "I have," said Mr. Wakley in a public speech—"I have foreworn medical practice. I use only the lancet, and that in the form of a quill." From that time he became the champion of medical reform of all kinds. If we turn to *The Times* of 1827 we find that at that early period *The Lancet* gave the first blow to "rapidity and corruption, by establishing a free medical press, and rousing the profession to a sense of its injuries and indignities, and to a spirit of resistance." Mr. Wakley's great aim was always to uphold the rights of the profession as a whole by the adoption of straightforward courses of action. What has he gained for medical men? In former days, when scarcely a week passed without furnishing instances of imbecility and ignorance on the part of coroners, and the reports of insults borne by medical men who were, without fee or reward, compelled to attend these "worthless, expensive, and pernicious exhibitions," he raised his voice with no uncertain sound against such palpable abuses, and earned for himself no small share of obloquy from those who considered

themselves injured by his fearless exposure of base principles. Unmistakable deaths from poisoning were recorded by coroner's juries from time to time as "Deaths by the visitation of God." Abuses so apparent soon roused him to most energetic action, resulting in his candidature and election for the office of Coroner for the Western Division of Middlesex at the enormous cost to himself of many thousands of pounds. From that time *The Lancet* has consistently supported the appointment of medical coroners, and now scores of medical men occupy that position. The Coroners Act, allowing the appointment of a permanent deputy coroner, and the Medical Witnesses Bill were introduced to parliament on his instigation and passed in consequence of his exertions.

As a direct result of his personal patience, an inquiry into the flogging to death of a soldier at Hounslow Barracks led to the abolition of flogging in the army. His keenest shafts, however, were aimed at empiricism and cant. "*the prima materia of the devil*," as Carlyle called it. He hated shams, and loathed the feebleness which succumbs to mere authority. He succeeded to a great extent in rescuing the very institutions which were established to prevent quackery from the quagmire of empiricism into which they themselves had fallen. His attack on the faults and absurdities connected with medical education should render the medical student of to-day, perhaps more than anyone else, grateful to the founder of *The Lancet*, for it is through his instrumentality that every student has now secured to him able and earnest teachers, and the right of using freely the opportunities which public hospitals afford him for his improvement. The first great battle by which the rights of a free medical press were established was won by Mr. Wakley on their behalf. Up to the year 1825, no clinical lectures were delivered in the hospitals, and no reports of the cases which occurred in them were published. The famous action of Abernethy v. Wakley established the right of the medical journals to print public lectures, and was a triumph for the press, the influence of which has been great and lasting. With regard to the decision in the case of Bransby Cooper v. Wakley, Sir James Scarlett, the opposing counsel, admitted "that the example of this proceeding has given to the periodical press a triumph and an influence which it never had before."

Mr. Wakley was one of the first to urge upon his medical brethren the necessity for their being represented in Parliament by members of their own profession; and, ever ready to practice what he preached, he submitted himself as Parliamentary candidate for Finsbury. Twice he went to the poll, and twice was he defeated. Undaunted, he went again to the poll at the next election, and was returned by an overwhelming majority. Before he had been many weeks in the House he began to manifest his care for the interests of the profession by asking questions of the greatest importance to its members, and throughout the whole of his Parliamentary career of twenty-four years was he the staunch champion of medical men, influencing the House to appoint select committees to inquire into abuses, introducing Bills, moving amendments, and in many other ways acting in their interests. He established a life assurance office for the pur-

pose of enforcing the payment by the various offices of the fees for the medical examination of their clients, urging that, as medical reports were given in the interests of the offices, payment of the fees should therefore be made by them. What is the direct result of this action at the present day? Every office now pays the medical fees, and I observed in a recent issue of *The Lancet* that during the past year one office had paid as much as £50,000 in recognition of the services of medical officers. In his threefold capacity of Member of Parliament for Finsbury, Coroner for West Middlesex, and Editor of *The Lancet*, he wielded a power unequalled by any other man in the profession, and was not slow to use it for the advancement of its interests and welfare. Perhaps one of the most important public functions performed on behalf of the poor by Mr. Wakley was the establishment of an Analytical Commission which exposed the adulteration of food, and converted the press into an instrument of police by establishing in *The Lancet* the precedent of publishing, fearless of all legal consequences, the name and address of the establishment where adulteration was carried on. In many cases he would add: "This is the third article which we have found adulterated—the public should avoid the shop." As a result, legal actions bristled around him, but such was the genuineness of his work that in not a single instance was an unfavorable verdict recorded against him. Some years after the establishment of his Analytical Commission, an Act of Parliament was passed requiring the appointment of public analysts throughout every district of the country. The public benefits resulting from this work cannot, indeed, be overrated.

What did he gain by the exertion of his indomitable courage on behalf of his professional brethren? Either as plaintiff or as defendant in the law courts Mr. Wakley must have fought some twenty-five or thirty actions, contesting in his own person with some of the leading baristers of that day over matters connected with the advancement of the profession at so great a personal expense that on several occasions the very existence of *The Lancet* was imperilled. He lent his aid in reforming the Lunacy Laws, and was always the defender of the rights and privileges of the medical officers of the united services and of the Poor-law administration. He was the champion of the Fellows and Members of the Royal College of Surgeons, who were unfairly treated by a Council then wholly irresponsible and self-elective. In regard to this body he maintained that when a few individuals were appointed to watch over the interests of a large body of men, it was quite necessary, in order to secure upright conduct on their part, that the interests of those few should be identified with those of the many. To this end he labored, exposing and denouncing the procedure of the "minacious oligarchy of our mismanaged temple," as he called the Council, and characterizing certain of the By-Laws then in force as "instruments of corporate iniquity." To attack abuses uncompromisingly wherever they existed, to spare no effort, toil, or trouble to effect reforms wherever they were required, to raise the profession as a whole from the lowly position it then occupied to such a level as it has

now attained in public esteem, where some of the labors of a life remarkable at once for uprightness and disinterestedness of purpose.

I've heard of hearts unkind
Kind deeds with cold returning
Alas! the gratitude of men
Hath often left me mourning

The memory of Thomas Wakley should be written in letters of gold on the mind of every medical man. Examples and principles such as these are surely those which all should be proud to follow and adopt, for even now necessity for further reform in each and all of the directions I have indicated is not wanting. I earnestly hope and believe that you, the successors of so worthy an ancestor, will persist in the noble endeavor to carry out the promise made at the time when he ceased to labor among us, and in so doing—though you may easily fall short of the rare excellence which he at all times displayed—nevertheless you will have adopted a course which shall be honorable alike to yourselves and of the highest utility to the noble profession you have the honor to represent.

THE ELEVENTH ANNUAL REPORT OF THE NEW YORK STATE BOARD OF HEALTH.

Doubtless the most interesting point in the report of the State Board of Health for last year is the statement concerning the effects of the influenza which prevailed a year ago. According to the report, the number of deaths in January, 1890, was 13,000—larger than ever before and 5,000 in excess of the average for that month for five years. This increase is considered to have been undoubtedly due to the epidemic. There were 3.51 deaths per 1,000 population from zymotic diseases during 1890, against 3.90 in 1889. Typhoid fever had a lower mortality. Diphtheria also seems steadily to have declined in prevalence. Small-pox caused only four deaths during the year, two of which were reported from New York City, the others occurring in Cohoes and Dansville. Consumption caused about 12 per cent. of all deaths.

PROGRESS IN THE RIGHT DIRECTION.

A comparison of the Seventh Report of the Illinois State Board of Health, on Medical Education, with the one for 1890, shows that some marked changes have taken place in the past year, and when a review is made of the changes for the better since the session of 1882-1883, there is much cause for congratulation and encouragement. There are now 148 medical colleges of all kinds in existence in the United States and Canada, there being 135 in this country and 13 in Canada. In 1882 the number of colleges requiring certain educational qualifications for matriculation was 45; in 1886, 114; in 1889, 117; in 1890, 124; and in this report 129.

In 1882 the number of colleges that required attendance on three or more courses of lectures before graduation was 22; in 1886, 41; in 1889, 47; in 1890, 64; in this Report, 85. Of the 148 colleges all have chairs of hygiene except 14, making 123 that teach this branch, while 119 now have chairs of medical jurisprudence.

PRACTICAL NOTES.

FOR NASAL CATARRH.

A writer in *L'Union Méd.* states that the following prescription is much used in London hospitals:

R. Ammonii chlorid., 30.0.
Sodii chlorat., 75.00. ℞.

Sig. A teaspoonful to a glass of water, to be used twice daily as a nasal douche in post-nasal catarrh combined with deafness.

—*The College and Clinical Record.*

TO RELIEVE NAUSEA AND VOMITING.

A writer in the *Therap. Gazette* states that a mixture of 1 part of menthol, 20 parts of alcohol and 30 parts of simple syrup, will relieve nausea and vomiting—sometimes even the obstinate vomiting of pregnancy—if given in teaspoonful doses every hour.

TO PRODUCE ANÆSTHESIA OF THE SKIN.

A spray of chloroform, 10 parts; ether, 15; menthol, 1 part, produces complete anesthesia of the skin, lasting for from two to six minutes.—*Pittsburg Med. Review.*

AN OINTMENT FOR PRURITUS OF THE ANUS AND VULVA.

Balfour reports that he has almost never failed to obtain relief, in cases of pruritus of the anus and vulva, from an ointment containing 80 grs. of calomel to the oz. of vaseline or other unguent.

FOR FURUNCULAR AFFECTIONS.

R. Menthol, gr. x.
Cocaine hydrochlorat., gr. v.
Ung. resinæ, ʒj. ℞.

—Shoemaker.

MIGRAINE.

The following powder is recommended in *La Méd. Moderne* for migraine:

R. Citrate of caffeine, 1½ gr.
Phenacetin, 2 grs.
Sugar of milk, 4 grs. ℞.

To be repeated, if necessary, in two hours.

WHEN SHOULD MEDICINE BE TAKEN?

The editor of the *Medical Summary* for November thus discourses on this topic: The proper time for the administration of medicines is of equal importance, in many instances, with the selection of the medicine itself. The sooner physicians realize this fact the better for the patients. A large number of medicines are used in a routine way, after meals; but too often, when so employed, they are not properly absorbed, or they hinder digestion, and thus undermine the foundations of nutrition. For example, if the Lomides be given after meals their absorption is

hindered, and their presence in the stomach interferes with the peptic ferment; so that, in addition to the depression caused by the bromide treatment, we have superadded that which follows derangements of digestion. Some medicines can be taken at any time, because of their diffusibility; other medicaments, in order to produce good results, should be exhibited after meals; and others again should be used only between meals, when the stomach is presumed to be empty. The administration of pepsin and pancreatin furnish excellent illustrations of these principles. When the secretions of the stomach are sufficiently acid, pepsin alone can be used in the course of half an hour after food; but if there be a lack of acidity, it will be advisable to combine the pepsin with an acid, preferably hydrochloric acid, which is the normal acid of the stomach. Should gastric digestion be slow or imperfect, a little more acid can be added from time to time, although there will be no need of increasing the amount of pepsin provided the peptones are taken up. In the use of pancreatin, on the other hand, the acid condition of the stomach will destroy its activity. This will not take place, however, if the pancreatin be taken with food just after the first mouthful is swallowed, or if the preparation be taken about two or two and a half hours after, when the contents of the stomach are supposed to be neutral in reaction.—*Medical Age.*

THE SPEEDY CURE OF TONSILLITIS.

The *London Medical Recorder*, October, contains the following prescription for the rapid relief of tonsillitis:

R. Tinct. of veratrum viride, 30 minims.
Sulphate of morphia, 1½ gr.
Distilled water, 6 drachms

℞. Dose, one teaspoonful, given twice, with one hour's interval, at the outset of the treatment, and then at intervals of two or three hours, as may be required.

The author of the treatment holds that there is some kind of therapeutical agreement or harmony between the drugs, when used together, which gives them an efficiency not possessed by either of them when used separately. For example, the liability to nausea from either of them alone is greatly modified by the combination. He refers to a number of cases in which this treatment has seemed to produce unusually prompt relief, and he asserts that he knows of no drug or drugs which have the power to control tonsillar inflammation with the certainty and celerity of those agents when used jointly.

PRESCRIPTION FOR A CORYZA POWDER.

The *Lyon Médical* offers the following powder for inhalation in coryza: Menthol, 1 part, mixed with roughly powdered roasted coffee, 50 parts. Another contains menthol, 2 parts; hydrochlorate of cocaine, 1 part; and boric acid, 100 parts.

SOCIETY PROCEEDINGS.

Buffalo Medical and Surgical Association.

Meeting of January 5, 1891.

THE PRESIDENT, DR. A. A. HUBBELL, IN THE CHAIR.

DR. GEO. E. FELL read a paper on

FORCED RESPIRATION.

(See page 325.)

DR. HARTWIG said he regarded Dr. Fell's accomplishments as being of lasting value to the profession. He considered the use of the face-mask preferable in average cases of forced respiration, because it dispensed with the tracheotomy, which, of course, was not so readily carried out.

He alluded to Schultz's method of artificial respiration by swinging the patient. He was convinced, from his own observation and experience, that infants who were not too heavy to handle, could be revived in every instance where there was heart beat remaining, by that method; and reported a case in which he had, after working half an hour at a stretch before obtaining the first gasp, revived a child; though it died some thirty-six hours later from pneumonia induced by fluids entering the lungs. For larger persons there was no method comparable with forced respiration.

DR. PHELPS reported a case of forced respiration performed by himself and Dr. Mann, some eight or ten years ago, by introducing a catheter into the larynx of an infant still born after a very troublesome breech presentation. They took turns, one blowing air from his lungs through the catheter, while the other applied pressure to the chest to force the air out. After two hours' continuous work the child breathed all right, and lived for several hours.

DR. ELI H. LONG: I want to thank Dr. Fell for his address this evening. I do not know but that I have done the Doctor the injustice of indifference to the claims of his method. I have refrained from criticism, but I must confess that I have not given it the attention which I probably ought to have done; and therefore I am all the more surprised and pleased at his explanation of it this evening. I believe very firmly in forced respiration, and with my experience with asphyxiated infants I am convinced that such cases can be saved by it that cannot be saved in any other way.

Dr. Long reported a case of severe asphyxia following a breech presentation, in which, after the use of the catheter in the larynx and supplying air from his own lungs, he had the child breathing after three fourths of an hour's work. The child lived twelve days. He had also had the pleasure of seeing infants live and thrive in

several other cases in which he had resorted to the method of blowing the air directly from his mouth into that of the child, without the catheter.

DR. W. H. BERGTOLD: A remarkable case occurred in the experience of some friends of mine, which I think I can with propriety say a few words upon. It was the case of a boy who was brought into the hospital having every sign and symptom of tubercular meningitis. He was taken one afternoon, about one o'clock, with entire stoppage of respiration, suddenly, and with no premonitory symptoms whatever. The heart continued beating, firm, strong and regular. The house staff performed artificial respiration on him by Sylvester's method for four hours. The heart continued to beat during this time. When the house staff became pretty well tired out, the trachea was incised and a tube put in, with a sort of bellows arrangement. I do not know how nearly it compares with Dr. Fell's, because I have never examined his, and know nothing about its construction. Altogether this boy was kept alive twelve hours from the time his respiration first stopped. At the post-mortem, which I made the day after, it was found he had the most marked tubercular meningitis. The ventricles were enormously dilated, and there was only about three-fourths of an inch of cerebral tissue left from the cortex down into the ventricles. All of the contiguous tissue was absolutely diffident. It was not softened, but it was almost like pus, and the medulla was also involved in this process. This case, of course, was absolutely hopeless because of the involvement of the respiratory centre in this process of sloughing. But it illustrates very beautifully what forced respiration will do, and it shows that Dr. Fell certainly did us a very great service in showing us how much can be accomplished by it.

DR. BARTLETT objected to the practice often resorted to and advised, of keeping patients in motion when suffering from an over-dose of morphia. He strongly recommended flagellation, which he had used for many years with good results, and for other than severe cases he considered it one of the best of methods. In severe cases there was probably no method which would compare with forced respiration.

DR. HARTWIG: I would like to ask Dr. Fell whether he would not be afraid of injecting alcohol or ether into a large vein on account of the possibility of thrombosis?

DR. FELL: If such a procedure were attempted at all, it should be done with the greatest precaution, and very slowly injected. In the case of J. B. we injected 8 ozs. of a normal salt solution, and I believe it would be safe to inject the smaller amount of brandy and ether which would be injected by the hypodermic method.

Regarding these other methods of artificial respiration, one significant point I wish to mention

is that forced respiration is more easily applied than any of them, even in infants, if you have the simple apparatus. Then again, in blowing air from the lungs of an attendant by the way of the tracheal tube, it must be recognized that the air passes to the lungs of the patient contaminated with carbon dioxide; we do not pass pure air into the lungs, and cannot expect as good results. It seems to me that Schultz' method would be pretty hard on the child, and harder on the practitioner—and that is the great objection to artificial respiration generally. Furthermore, regarding these vigorous methods, I believe that a great many cases are lost through them. In cases, for instance, where the asphyxia has been long continued, the bare fact of moving the patient about might in many cases produce just the condition which would cause death, through the loss of energy to the muscular tissues of the body; and the heart tissue also.

In narcotized subjects, I believe that means should be used in conjunction with the forced respiration, for combating the poison—atropia, digitalis, and every other means applicable. I think it of very great importance to keep up the energy of the system, even with the use of nutritive material, which will sometimes help greatly.

As to forced respiration being necessary in desperate cases only, if you have the apparatus, it should always be used in preference to artificial respiration because it accomplishes more, and is not conducted at the loss of the patient's energy, and is also less tiresome and easier to apply. As to flagellation, I do not know how valuable it is, but it seems to me that there are cases in which it would be of no value whatever, where forced respiration would be of great value. Only those who have witnessed the effects of forced respiration in a serious case can fully appreciate the full extent of its influence upon the system.

Another point that needs to be considered is, that it is not always the quality or the quantity of the narcotic poison taken that is of the first importance; but how long has the poisonous influence existed? For instance, a grain of morphia interferes with respiration and produces a cyanotic condition, with the heart tissue and the muscular tissue of the body losing energy through the asphyxiated condition. There you have an influence entirely outside of the influence of the poison, which indeed may be the controlling factor in the question as to whether the patient will live or not.

DR. BARTLETT: Will Dr. Fell kindly express his opinion as to the advisability of keeping the patient in motion?

DR. FELL: I think it inadvisable. After forced respiration is instituted the entire energy of the patient should be saved as far as possible, in my opinion. All that is required is to eliminate the poison and to supply the blood with

oxygen. Do that in the easiest way possible, and you are doing all that can be done, except the using of antidotes advisedly. In opium poisoning it is always very important to catheterize the patient. Opium and morphia being eliminated mostly by the kidneys, this should never be forgotten, nor the injection of water into the rectum, and the administration of water to drink. As the poison is also eliminated by the stomach it may be advisable in some cases to carefully wash it out, but do not let any fluids pass to the lungs. In this way the patient will probably be enabled to eliminate the poison more quickly than by any other means.

DR. DORR: Do you from your experience, and from the case of this patient mentioned, think that those abscesses were caused by the brandy and ether or by a bad needle and infected instrument?

DR. FELL: I believe that the abscesses were caused by the brandy and ether, merely because after a few days there were circumscribed areas all over the region where the injections had been deposited.

DR. DORR: Merely because the capillary circulation was weak?

DR. FELL: Very weak, almost inert, owing to small quantity of blood in the system. I thought at first from rapid breathing it was pneumonia. Another fact worthy of mention is, that in none of these cases has pneumonia or any bronchitis been produced, not even in B's case, the indications were caused by pain over the region of hypodermic medication.

DR. DORR: Have you ever seen in any other case brandy and ether produce abscess?

DR. FELL: I never have.

DR. DORR: It is peculiar if it does in just this condition, because I have never seen it in any other condition.

DR. FELL: I believe it was entirely owing to the fact that the patient had lost so large an amount of blood. The capillary circulation must have been insufficient to carry off the brandy and ether.

DR. DORR: That is quite a physiological point.

DR. FELL: Another point I wish to emphasize is the adaptability of forced respiration in drowning and cases of asphyxia from whatever cause. The drift of this discussion may give the impression that it is more useful in cases of opium poisoning than other cases of asphyxia.

THE PRESIDENT, DR. A. A. HUBBELL: I am sure we are satisfied of one thing, gentlemen, and that is that Dr. Fell can give us a good deal of light on the subject of opium poisoning and all cases of asphyxia, and his remedy certainly deserves a great deal of commendation, as it has in fact received it by so eminent an authority as Dr. H. C. Wood, of Philadelphia, and in such a public way.

FOREIGN CORRESPONDENCE.

LETTER FROM PARIS.

(FROM OUR OWN CORRESPONDENT.)

Koch's Lymph in the Hospitals and Laboratories of Paris—The Library of a French Doctor in 1609—Compulsory Revaccination of Medical and Pharmaceutical Students—Post-Guillotine Phenomena Observed in the Body of Eyraud—Portable Field-Dressings for French Soldiers—Hygiene at the Hair-Dressers.

The latest judgment passed by our leading medical authorities on this new treatment of tuberculosis are not of a favorable nature. The most sweeping condemnation of the method emanates from Professor Verneuil, the veteran surgeon of the Hotel Dieu, (formerly of La Pitié). At a clinical lecture recently delivered, the Professor summarizes the results yielded by Koch's treatment as follows:

- | | |
|---|---|
| 1. Genuine and lasting cures—still unknown. | 7. Serious complications set up in normal or non-tuberculous organs—frequent. |
| 2. Temporary improvement—a few instances. | 8. Early fatal complications from local aggravation or the setting up of lesions of hitherto healthy viscera—already very numerous. Virchow having made 25 autopsies. |
| 3. Improvement of any reasonable duration—much rarer. | 9. Remote complications ending fatally—several already noted. |
| 4. Condition stationary after weeks of treatment—very common. | |
| 5. Temporary, but more or less serious local aggravation—ordinary result. | |
| 6. Persistent local aggravation—of common occurrence. | |

As regards the diagnostic value of the lymph, he disparages it on the ground of its uncertainty, and the danger inseparable from the inoculatory process. He asserts that, in the immense majority of cases, ordinary clinical and bacteriological examination suffice amply to elucidate the true nature of tuberculous affections, and he opines that, even when these diagnostic means fail, it is wise to abstain from the employment of the lymph.

We still await the collective report of the committee appointed at St. Louis Hospital to study the clinical effects of the lymph. M. Vidal, one of its members, has made (Soc. de Dermatologie et de Syphiligraphie, January 15) an anticipatory report which reveals no new facts, excepting the supervention in the course of the treatment of myocarditis and endocarditis. Great caution has been observed in the dosage, each patient receiving only one-half milligram, and the dose being increased by the same quantity till the temperature reaches 102.2° F., an interval of from four to eight days being allowed between each inoculation.

At the Académie de Médecine (February 10) Professor Jaccoud reported the results obtained from the inoculation of guinea pigs with Koch's lymph. A robust Angora guinea pig, weighing 580 grams, received in two series of inoculations (separated by an interval of a week), and extending over ten and eight days respectively, a quan-

tity of pure lymph equal to 50 centigrams. The only effect observed was a loss of weight of 26 grams. The day following the last inoculation the animal was inoculated over the right shoulder with one-half of a tuberculous gland furnished by another guinea pig. A month later the animal died, weighing only 450 grams. The autopsy revealed the presence of tuberculous glands in both axillæ, confluent grey tubercles in both lungs, hepatization of right apex, and caseous masses in the liver and spleen. The experiment was controlled by the simultaneous inoculation of a test guinea pig with the other half of the tuberculous gland. This animal has lost 88 grams in weight and has developed tuberculous glands in the axillæ, but he has already survived his Kochined comrade by six days. Dr. Dujardin-Beaumetz has likewise treated tuberculous guinea pigs with the lymph, but this treatment did not prevent the animals dying, as usual, when they had lost one-third of their weight. The same fatal result ensued in the case of Kochined guinea pigs inoculated subsequently with tuberculous virus.

The following inventory of the somewhat meagre library of a whilom practitioner, one Richard Hunot, "*en son vivant médecin et bourgeois de Saint-Onen de Caen*," may interest your readers. As a rendering into modern English of this curious document would deprive the Rabelaisian phraseology of its author of its native piquancy, I transcribe it *in extenso*:

Le 27 janvier 1609, Guillaume Le Bailly, sergent royal "fit inventaire par répertoire des lettres, pièces d'escritures, ensemble de quelques livres demeurez du décès de defunct M. Richard Hunot, d'autant que j'en ay trouvé tant dens l'une des armoires, ung buffet que dens ung petit coffret." L'inventaire établit de nouveau l'excellente situation du défunt: quant à la bibliothèque, elle est bien peu volumineuse:

Item ung grand livre convert de blanc, intitulé Les pourtraicts anatomiques de toutes les parties du corps humain, gravés en tailles dorées;

Item ung autre grand livre couvert de rouge, intitulé Les œuvres de Aubroise Paré, conseiller et premier chirurgien du Roy;

Autre livre couvert de parchemin intitulé Les voyages du s^r de Vilarnout;

Autre livre couvert de rouge intitulé Les institutions chirurgiques de Jean Trigault, docteur en médecine;

Autre viel livre sans intitullacion commençant: puisque j'auray rendu graces à Dieu qui donne vie, etc.;

Autre petit livre intitulé Traicté de la nature et curation des plaies de pistollé et arquebuses;

Autre livre intitulé: La chirurgie mise en théorie et pratique;

Autre livre en latin intitulé Petit pontamy eccey burgensis (sic), etc.;

Item autre petit livre couvert de blanc intitulé Le guidon des apothicqères;

Autre viel petit livre intitulé Le grand Albert.

According to the terms of a ministerial decree, dated January 1, 1891, all students of medicine and pharmacy throughout France are compelled, before their names are allowed to be entered on the rolls of their several faculties or schools, to produce a certificate of revaccination performed

under the control of the faculty or school at which the aspirant desires to prosecute his studies. This prophylactic measure is, moreover, rendered incumbent on students already on the books before they can take out further *inscriptions* (sixteen inscriptions are necessary for the doctorate). Apropos of this excellent regulation, I may mention that a strong current is setting in among French hygienists in favor of compulsory vaccination and even revaccination for all classes of society. The subject has been hotly discussed for the last few weeks at the Académie de Médecine in connection with the "depopulation" so-called of France. It is strange to hear such an enlightened personage as Professor Le Fort rejecting such a wise precaution as an infringement of the liberty of the citizen. On the other hand, Brouardel, Proust, Colin, Hervieux are all in favor of the primary and the secondary operations being rendered more vigorous in their application, rightly regarding the forcible isolation of venereal patients advocated by M. Le Fort as a greater violation of individual liberty than the innocuous and much more effective practice of vaccination.

The late Paul Loye maintained that decapitation put an immediate stop to all vital phenomena. M. Laborde had the opportunity of noting in the case of the notorious assassin of the process-server Gouffe, the occurrence of the following phenomena, the presence of which disproves the above assertion. Immediately after the execution there was noted marked corrugation of the forehead extending to the vertex; associated ocular movements; opening and shutting movement of the mouth of a respiratory type. The palpebral reflex could be plainly evoked for from fifteen to twenty minutes after decapitation, during which time the iris remained sensible to the stimulus of light. Simultaneously with the deposit of the trunk in the basket there were noticed up and down movements of the arms, plainly visible despite the fact that they were firmly ligatured to the sides. This phenomena is, it appears, well known to Deibler's assistants, who, in their figurative language denominate it "the flapping of the wings." The feet were strongly retracted, and when M. Laborde pinched the arm, the trunk being in the basket, a reflex movement was very apparent. As M. Laborde remarks, these reflex movements are strictly analogous to those perceived in the abattoirs, where the stimulation of a member immediately after felling produces a violent kick.

The Minister of War has decreed that each officer and private shall receive, in the event of mobilization, a field dressing to be carried in the inside pocket of his dolman, waistcoat or hood. The small packet, shaped like a flat pocket-book, is composed of: 1. An outer covering of cotton stuff; 2. An inner envelope of macintosh; 3. A

cake of cotton wool rendered antiseptic by a previous steeping in a 1 per 1,000 solution of corrosive sublimate. This cake is wrapped up in gauze and can, if need be, be divided into two layers for a double dressing (entrance and exit wounds by bullets); 4. A small compress of silk gauze, also asepticised by sublimate; 5. A fragment of macintosh to prevent the drying of the dressings when applied; 6. A gauze bandage, also sublimate, six centimetres broad by 7 metres long; 7. Some safety-pins wrapped in paper and deposited between the two envelopes so as to prevent the metal being attacked by the sublimate.

While on the subject of antiseptics, let me record the first instance known in this country, so renowned for its *coiffeurs*, of a barber applying the principles of surgical cleanliness to the purifying of the weapons with which he assails the faces and scalps of hirsute humanity. The name of this perfumed emulator of Lister is not stated, but he applies his aseptic scissors, razors and brushes at Lyons. His razors are mounted in aluminium, the scissors are nicked, the brushes being provided with bristles which are screwed on to the wood, thus avoiding the necessity for the employment of glue or stitches. After use, these instruments are well washed and then subjected to a temperature of 120° C. in an oven enclosed in a layer of glycerine heated by a range of gas jets.

Some time ago, the Board of Health of the Seine adopted, at the instance of M. Lancereaux, a resolution recommending similar precautions (the purifying of instruments used by hair-dressers by means of the flame of a spirit-lamp, and antiseptic solutions). This resolution has, I believe, remained a dead letter, and the public continues to run the risk of contracting various parasitic cutaneous diseases, not to mention syphilis, at the hands of "capillary artists" unacquainted with, or careless of, these dangers. All honour, then, to the pioneer of *fin de siècle* shearing who is the subject of this article!

J. H. B.

NECROLOGY.

Dr. Hosmer Allen Johnson.

Dr. Hosmer Allen Johnson was born not far from Buffalo, N. Y., in a town called Wales. Here he lived until about 10 years of age, enjoying those advantages for early boy life which spring from a home filled with elevating influences, and from contact with the phenomena of rural nature. It was interesting to note how this early study of the beautiful in nature acted like a lofty education, and impressed itself on the whole tone of his mind. Near his early home there is a hill range of considerable height. Its

rocks are carved by streams into gorges, decorated with mosses and wild flowers and crowned with woods. Here the boy, Hosmer Johnson, used to wander and climb, studying the beauty of the views, and filling his memory with pictures which tinted all his after life and were never effaced by the larger views of other regions. Here he learned to love nature, and to realize how its magnificence typifies the glory of its Creator.

These sentiments never died out. On the contrary, they strengthened with his growth, and helped to form in him that pure and elevated taste which gave such a charm to his whole career.

It was this which caused him to select a scientific profession, as well as to study nature for a recreation. He traversed wild rivers in a canoe, sleeping in the forests; he climbed the White Mountains on foot, and rolling himself in a blanket, slept under the stars with a friend or two at his side. The same feeling led him to explore Switzerland, California, Colorado, and the mountains about Puget's Sound.

These memories prompted him when he assisted to found the Chicago Academy of Sciences and the Astronomical Society, and led him to say and do all he could to encourage the study of natural objects. Such results are worthy of thought at a period when the growth of cities is more and more shutting men out of nature. Perhaps if we could bring more children under the influences which molded the youth of Johnson, we would have more such men in after life.

At the age of about ten years he removed to Almont, Mich., and helped cut a farm out of the woods, at a time when wolves and Indians were far more abundant than civilized beings. During this period an attack of sickness left him with an irritation of the bronchial tubes which never fully left him, and caused many of his acquaintances to suppose for fifty years that he was on the verge of consumption. There was, however, not the slightest tendency to tuberculosis in any part of his body, but the pulmonary irritation subjected him to repeated attacks of pneumonia, and it was one of these which at last caused his death at the age of sixty-eight years. In his early manhood he expected only a short life, and scarcely dreamed of attaining the age which he finally reached.

In the year 1841 he entered an academy at Romeo, Mich., where he prepared for college, and then entered the University of Michigan, from which he graduated in 1849.

His educational career showed a remarkable talent for the acquisition of languages, both ancient and modern, and he studied Latin, Greek, Hebrew, French, German, Italian, and to some extent, Spanish. In his boyhood he also picked up, from the surrounding Indians, a considerable practical knowledge of the Ojibway tongue. Three years after taking his A.B. he received the

degree of A.M., and at a later period that of LL.D.

After graduation he went to Chicago and commenced the study of medicine under the supervision of Prof. Herrick. In 1851 he became the first interne of Mercy Hospital, and in 1852 graduated in Rush Medical College. In 1853 he became a member of the Faculty, and continued with it until 1858, when he resigned. Not long after his resignation he united with a few others in founding the Chicago Medical College, in which he was a professor and trustee from the beginning to the day of his death, and was the first president of the faculty.

His zeal for the study of nature led him to become one of the founders of the Chicago Academy of Sciences, as well as of the Historical Society, and of the Astronomical Society.

He was for some years editor of the *Northwestern Medical Journal*, and afterwards a member of the City, State and National Boards of Health. During the war of the rebellion he was commissioned by the Governor, with the rank of Major, as one of the Board for examining surgeons and assistant surgeons for the Illinois regiments, and such was the faithfulness of the Board that the medical officers of Illinois were conspicuous in the whole army for their thorough knowledge, and their humane and skilful conduct on the field of battle. In examining assistant surgeons for promotion, he had to traverse the field of war, and his duties brought him occasionally under fire, at which times he showed his skill as an operator and as a manager of field ambulance service.

After the great Chicago fire, Dr. Johnson was one of the chief managers of the Relief and Aid Society, which distributed millions of dollars of property among the sufferers.

He married Miss Margaret Seward, a relative of the New York statesman, William H. Seward. He had two children, of whom only one survived him, Dr. Frank S. Johnson, Professor of Pathology in Chicago Medical College.

Dr. Johnson was much more than simply an eminent physician. He was a magnificent man, possessing a clear, trenchant intellect, and a great and noble heart. His reputation is without spot, and his honor without stain.

HOSMER A. JOHNSON
OBIT FEB 27 1891.

We mourn for him whose life has flown
Out from its fragile shell of clay.
Into the nightless, perfect day.
To reap the fruit that here was sown
Not all the good of earth, die young
Of him no truthful tongue spoke ill,
And praises to his gentle skill
By twice ten thousand hearts are sung.
For him no banners drape the air,
No half-mast flags droop in the blue;
But tears shall fall as evening dew,
And science garb of mourning wear
No need of shaft to mark the bed
Wherein his dust dissolves in dust—
Fair science keeps her own in trust,
If they but walked where Nature led.

No nation honors those that stand
And battle with the living dead—
The stalking plague and poisonous breath
More fatal than the foe-man's brand.

No rifled gun nor keen-edged sword
Can reach the enemy he fought;
Death in its ghastliest form he sought,
Yet not for honor nor award.

'Twixt Death and human kind he stood—
Let fame on such no longer frown.
For deeds of blood award no crown,
But rather for the doing good.

Man's friend he was; foes had he none
In fruitful youth or ripened age—
His life a clear and bloodless page
Of noble deeds more nobly done.

No bias warped his balanced mind
To superstition ne'er a slave;
Let this be written o'er his grave:
"He gave his life to all Mankind."

Such men kind Nature ever needs
To reason from effect to cause;
Yet shows them only half her laws,
To spur them on to nobler deeds.

For these the stony paths she smooths,
And guides her children in the night,
While far beyond she hangs the light
That lures them on to greater truths.

What need his virtues to portray?
What need his memory to defend?
As patriot, healer, sage and friend
He walked in his Great Master's way.

WILLIAM G. EGGLESTON.

Springfield, Ill., Feb. 27, 1891.

SPECIAL CORRESPONDENCE.

An Act Pending in Congress of Interest to the Medical Profession.

To the Editor:—The chief provision and object of a measure now pending in Congress, and subject to action at an early date, is that requiring all articles publicly sold for consumption or use to show upon the container the nature, or name of the contents.

The Bill, having a strong and influential commercial backing, came near passing when first presented, and early in the session, but was made, with all other legislation, to give way for tariff politics, but not until it had aroused a furor of alarm among a class against whom it was not aimed, but were in its line of effect. These were proprietary, and the whole swarm of patent medicine frauds.

Is not this the time to see that these evils, enemies of the public—infinite worse than an oleomargarine operator—do not escape the just application of so reasonable and *unavailable* regulation. Floods of the most potent and poisonous articles whose effects every practitioner is called to relieve, are sold with no evidence or means of judging its character, thus obliging us blindly to prescribe, or select an antidote.

The deadly results from the use of substances for food and medical purposes are becoming of alarming and increasing frequency.

No exceptions should be made in this Act now before Congress, and medical men are already discerning the penalties which torpor and inattention upon the part of the profession has incurred. The public robbed, swindled, and injured in health—not to say fatally imposed upon by the unrestricted and unchallenged purveyors of death and disease in the guise referred to. Medical men are held responsible for their dispensing by the files of the druggists, whose convenience in cases of carelessness or accident is often proven, while the veriest ignoramus may, under copyright protection, sell the most potent drug and disguise its character by any term he may choose to adopt.

H. C. MARKHAM, M.D.

Independence, Iowa, Feb. 19, 1891.

The Association of Military Surgeons of the Wisconsin National Guard.

To the Editor:—In response to a call from the Surgeon-General, N. Senn, for February 26, 1891, the surgeons of the Wisconsin National Guard met in Milwaukee for the purpose of organizing an association for the advancement of military and accidental surgery and to be called "The Association of Military Surgeons of the Wisconsin National Guard." The work of the Association will be clinical, experimental, original, etc., pertaining to military surgery. Surgeon-General Nicholas Senn was elected President; Major F. J. Wilkes, 2nd Reg. W. N. G., Vice-President; Lieutenant Ralph Chandler, 1st Light Battery W. N. G., Secretary and Treasurer.

The surgeons responded to a man. The Association has a membership of fifteen and will meet once every four months.

The day was spent very profitably in clinical work at the Milwaukee Hospital, Soldier's Home Hospital, and in demonstrative and experimental work in intestinal surgery and gun-shot wounds of the abdomen, on dogs, at the Milwaukee County Hospital. Each member was given an opportunity to exercise his skill in suturing intestinal wounds. At 8 P.M. the surgeons assembled at the Republican House, where an elaborate banquet was tendered by Surgeon-General N. Senn. Toasts were given and the wee small hours were long on their way ere the surgeons had fully vanquished the enemy.

All await with pleasure the announcement of the next meeting. It is hoped that this will be a stimulus to surgeons of other States to form similar organizations with a view of eventually calling a National one.

Efforts will be made to fill vacancies in the medical department of the W. N. G. as they occur, by a competitive examination.

RALPH CHANDLER,
Lieut. and Asst. Surg. 1st Lt. Battery, W. N. G.,
Sec'y and Treas.

Milwaukee, Feb. 28, 1891.

Shall The Journal be Removed to Washington?

To the Editor:—The arguments for removal are: 1. Our JOURNAL has a name distinctive of its nationality, and inasmuch as it represents, or is intended to represent the status of the medical profession of this country, it would seem as if its seat ought to be at the Capital, which, though not the geographical centre, is really the centre from which our whole system of National economy radiates. 2. The Library of the Association and the ever increasing National Library, and the Army Medical Museum are there, and always at hand for the use of the editorial department. 3. The Army, Navy and Marine-Hospital medical and surgical news are there and easily available. 4. National pride may say to many: "Place the National Journal in the National Capital."

Against removal: 1. The JOURNAL, although born in Cleveland, O., was immediately taken to Chicago, where it was carefully nurtured during its infancy, and where it rapidly grew into its present state of vigorous adolescence. It has become acclimated to the soil of Illinois, and will for the present, other things being equal, no doubt do better there, and reach a vigorous manhood much earlier than if stunted by transplantation; no matter how well the new soil may be adapted to its reception. 2. The personnel of THE JOURNAL may be equally as good and efficient in Chicago as in Washington, and the removal of the material would be attended with a loss that cannot as well be afforded at present as in the future, especially if the management of its financial relations continues as successful in the future as in the past. 3. Chicago is much nearer the centre of our population than any Eastern city, and will continue for some years to become more so, and will annually get a larger increase to the subscription list of THE JOURNAL from the West, in proportion to present population, than from the East.

My conclusions are, after weighing carefully the arguments for and against, that as *THE JOURNAL* has made a phenomenally rapid growth in Chicago it should remain there. One of the fathers of the American Medical Association and the first editor of *THE JOURNAL* lives in Chicago. He is robed in honor; *THE JOURNAL* was his pet. Let it remain there, at least, while he lives.

E. GRISWOLD, M.D.

Sharon, Pa., Feb. 23, 1891.

To the Editor:—I can see nothing to be gained by removing *THE JOURNAL* to Washington, D. C.; while, on the other hand, by so doing you leave one of the best medical centres in the world, and take *THE JOURNAL* to the extreme border of its circulation, thereby depriving many of its readers of its reading for many days after publication. If there is any necessity for moving *THE JOURNAL* from Chicago, I would be in favor of St. Louis, or some equally good city located mid Continent, and if I consult my selfish choice, Chicago is preeminently that choice.

A. F. HUNTON, M.D.

W. Duluth, Minn., February 21, 1891.

To the Editor:—I have within the last week or ten days received two or three letters suggesting that the question of removing *THE JOURNAL* should be referred back to the Trustees, who have the power to act. And now comes the deponent, the *St. Louis Clinique* of February, 1891, who deposes and says, that "*we hope a motion will prevail to refer the question back to the TRUSTEES.*" But he precludes that assertion by saying that "the Board was given full power to act: by its act *THE JOURNAL* was located in Chicago, and by its authority it could remain or be removed." Very good. But will the said deponent tell the Court, who gave said Board this authority? And tell us whether the same body which extended the power in the first place, cannot rescind that power, or take up any subject referred to the Board of Trustees, and modify it to suit their liking?

It is simply the old story of whether the dog shall wag his own tail or whether the tail shall wag its own dog; and that question was overwhelmingly settled at New Orleans a few years ago, on the question of adopting the report of the Committee on organizing the Ninth International Congress, which at that time tried to convince this same Association that they had *been given power to act*, and the dog must be wagged by the tail; but the dog protested against this, and the result was the tail was wagged instead of the dog.

So with this or any other committee of a representative body; that body has the power to take up any question it has referred to any subcommittee, and settle it to suit the majority, and the Trustees acted wisely, and in accordance with parliamentary law and common usage, and former precedents, when they referred the matter of removing *THE JOURNAL* from Chicago to Washington, back to the Association.

Each Permanent Member of the Association and subscriber is an interested stockholder in *THE JOURNAL*, to the amount of five dollars a year, and has a perfect right to give an expression as to where he wants *THE JOURNAL* he supports published, and this expression should be a *guide-board* to the coming delegates of the next meeting, to direct them in their deliberations, who alone have a right to speak officially on all questions that pertain to the interests of the Association.

Again, permit us to correct the statement of the *Clinique* which says that the Trustees "have recommended that the change be made." *The Trustees as a body have not made any such recommendation.* That is what a certain faction of the Trustees wanted them to vote, but failed to secure such recommendation, and hence the "great controversy" which, the *Clinique* says, "is now being carried on regarding the proposed removal of *THE*

JOURNAL from its home in Chicago to Washington City."

R. HARVEY REED, M.D.

Mansfield, O., February 24, 1891.

To the Editor:—Relative to the removal of *THE JOURNAL* to Washington, D. C., I would say I can see no reason why it should not remain where it is, and think there are several valid reasons why it should.

WM. CASTON, M.D.

Spokane Falls, Wash., Feb. 25, 1891.

To the Editor:—You may add my vote to the Chicago column, relative to the site of your publication.

E. C. SPITZKA, M.D.

712 Lexington ave., New York.

To the Editor:—Why should *THE JOURNAL* go to Washington? The question is full of suggestion. Why should it have been established at Chicago? Clearly because it was a convenient centre, with no East and no West, whence it could most speedily communicate with all points.

Has it ceased to be our great central metropolis? Then Congress made a mistake in locating the world's greatest exposition.

Are paper, and ink, and printing presses no longer at its command, or have all the brains of the Nation gravitated to its Eastern slope?

We grant "the sun rises in the East to open and illumine the day," but she travels westward, and at high noon is its beauty and glory.

Whilst Chicago will long remain the central metropolis of America and the most convenient home for its great medical journal, no one section, no one man, will absorb all majesty or power.

Why should *THE JOURNAL* go to Washington?

W. L. SCHENCK, M.D.

Topeka, Kan., Feb. 28, 1891.

To the Editor:—Leave *THE JOURNAL*, where it properly belongs, in the business and population centre of the country—Chicago, Ill.

G. L. FRITCHETT, M.D.

Fairbury, Neb., February 27, 1891.

To the Editor:—I have heard and read many convincing reasons why *THE JOURNAL* may with advantage to the whole profession be edited and published in Chicago; but have so far failed, in answer to my enquiries, to discover any justification for its taking up house at the Capital.

It appears to me that the very advance guard of the Washington attack has not yet appeared in sight. In the meantime I suppose it is proper for us to know that when it does come to a comparison between the two cities as teaching centres, as sources of subscription, as sources of advertising patronage and as centres of medical population, most of them who cannot be accused of partizan-ship, and who are quite as much interested as we are, will decide at once in favor of Chicago.

In the meantime, will some promoter of the Washington scheme kindly give us a *resumé* of the superior advantages, temporal and spiritual, which *THE JOURNAL* is to enjoy after its advent in Washington?

But perhaps these are to be held back until the well-known hospitality and patriotic associations of the Federal city shall have had an opportunity to work their charms.

Still, in spite of these seductions, I expect, in common with the majority, to cast a vote for Chicago.

CASEY A. WOOD, M.D.

Chicago, Ill., Feb. 25, 1891.

To the Editor:—As an humble member in the rural ranks, I wish to enter my solemn protest against the removal of THE JOURNAL. Such an experiment would be child's play.

W. M. LEWIS, M.D.

Greensburg, Ky., Feb. 28, 1891.

MISCELLANY.

THE PHILADELPHIA POLYCLINIC.—At the annual meeting of the corporators of the Philadelphia Polyclinic held on January 12, 1891, the following new members were elected: John L. Wilson, James Hay, James P. Scott, Mrs. Thomas A. Scott, Mrs. Wm. Waldorf Astor, Roland B. Whitridge, M. D., Mrs. Matthew Baird, Mrs. Elizabeth H. Farnam, Dr. Thomas S. K. Morton, George W. Childs, Mrs. Moses Brown, H. H. Houston, Mrs. Isaac B. Thorn, and Rev. Wm. Neilson McVickar.

At the same meeting the Board of Trustees for 1891 was elected as follows: Charles K. Mills, John B. Roberts, Charles B. Baeder, Rev. G. Woolsey Hodge, H. H. Wilson, Rev. Wm. Neilson McVickar, Henry Lefmann, J. Henry C. Simes, Caleb C. Roberts, Hon. Wm. N. Ashman, Thos. S. K. Morton, H. Augustus Wilson.

MEETINGS OF MEDICAL SOCIETIES FOR 1891.—We are indebted to the *New York Medical Journal* for the following list of National and State Medical Societies, and the places and dates of their meetings for the current year.

For the convenience of those who may desire to consult it, we reproduce the list entire:

- Florida Medical Association, Pensacola, April 14 and 15.
- Medical Society of the State of Tennessee, Nashville, April 14, 15 and 16.
- Medical Association of the State of Alabama, Huntsville, April 14, 15, 16 and 17.
- Medical Association of Georgia, Augusta, April 15, 16 and 17.
- Iowa State Medical Society, Waterloo, April 15, 16 and 17.
- Medical Society of the State of California, Sacramento, April 21, 22 and 23.
- Medical Association of Montana, Helena, April 24 and 25.
- Medical and Chirurgical Faculty of Maryland, Baltimore, April 28, 29 and 30.
- Texas State Medical Association, Waco, April 28, 29 and 30, and May 1.
- State Medical Society of Arkansas, Hot Springs, April 29 and 30 and May 1.
- Medical Society of the State of Washington, Seattle, May 6, 7 and 8.
- Missouri State Medical Association, Excelsior Springs, May 12, 13 and 14.
- Indiana State Medical Society, Indianapolis, May 13, 14 and 15.
- Kansas Medical Society, Wichita, May 13, 14, 15 and 16.
- Illinois State Medical Society, Springfield, May 19, 20 and 21.
- West Virginia State Medical Society, Fairmount, May 20, 21 and 22.
- North Carolina State Medical Society, Asheville, May 26, 27 and 28.
- Connecticut Medical Society, Hartford, May 27, 28 and 29.
- Pennsylvania State Medical Society, Reading, June 2, 3, 4 and 5.
- State Medical Society of Wisconsin, Madison, June 3, 4 and 5.

- Delaware State Medical Society, Rehoboth, June 9 and 10.
- Maine Medical Association, Portland, June 9, 10 and 11.
- Massachusetts Medical Society, Boston, June 9 and 10.
- South Dakota State Medical Society, Chamberlin, June 10, 11 and 12.
- Rhode Island Medical Society, Providence, June 11 and 12.
- Michigan State Medical Society, Saginaw, June 11 and 12.
- New Hampshire Medical Society (centennial) Concord, June 15 and 16.
- Colorado State Medical Society, Denver, June 16 and 17.
- Ohio State Medical Society, Put-in Bay, June 17, 18 and 19.
- Minnesota State Medical Society, Minneapolis, June 18, 19 and 20.
- Medical Society of New Jersey, Long Branch, June 23 and 24.
- Vermont State Medical Society, Burlington, October 15 and 16.
- Mississippi Valley Medical Association, St. Louis, October 14, 15 and 16.
- Tri State Medical Association of Tennessee, Alabama and Georgia, Chattanooga, October (date to be fixed).
- Medical Society of Virginia, Lynchburg, October 27, 28 and 29 (subject to change).
- New York State Medical Association, New York, October 28, 29 and 30.
- Louisiana State Medical Society (place and date to be determined).

NATIONAL ASSOCIATIONS.

- American Academy of Medicine, Washington, May 2 and 4.
- American Medical Association, Washington, May 5, 6, 7 and 8.
- National Association of Railway Surgeons, Buffalo, N. Y., April 30 and May 1.
- American Gynecological Society, Washington, September 15, 16 and 17.
- American Orthopaedic Association, Washington, September 15, 16 and 17.
- American Association of Andrology and Syphilology, Washington, September 22, 23 and 24.
- Congress of American Physicians and Surgeons, Washington, September 22, 23, 24 and 25; in connection with this congress will be held the meetings of the American Climatological Association, American Ophthalmological Society, American Otological Society and American Neurological Association.
- American Dermatological Association, Washington, September 22, 23, 24 and 25.
- American Surgical Association, Washington, September 22, 23, 24 and 25.
- American Laryngological Association, Washington, September 23, 24 and 25.
- Southern Surgical and Gynecological Association, Richmond, November 10, 11 and 12.

Official List of Changes in the Stations and Duties of Officers Serving in the Medical Department, U. S. Army, from February 21, 1891, to February 27, 1891.

Capt. Alonzo R. Chapin, Asst. Surgeon, leave of absence granted in S. O. 17, Dept. of Dak., January 31, 1891, is extended one month. By direction of the Secretary of War. S. O. 41, A. G. O., February 26, 1891.

Lieut. Col. Blencowe E. Fryer, Asst. Medical Purveyor, having been found incapacitated by Army Retiring Board, on account of disability incident to the service, is, by direction of the President, retired from active service this date, under the provisions of Section 1251, Revised Statutes. Par. 15, S. O. 42, A. G. O., February 24, 1891.

The following named officers, having been found by Army Retiring Board incapacitated for active service on account of disability incident to the service, are, by direction of the President, retired from active service at this date, under the provisions of Section 1251, Revised Statutes. Capt. John de B. N. Gardiner, Asst. Surgeon, Capt. Robert W. Shufeldt, Asst. Surgeon. Par. 12, S. O. 43, A. G. O., Washington, February 25, 1891.

ADDRESSES.

PHTHISIS PULMONALIS.

An Address delivered before the King's County Medical Association.

BY WM. McCOLLOM, M.D.,

OF BROOKLYN, N. Y.

THE RETIRING PRESIDENT.

I have chosen as a subject for the address which I offer you this evening, the very old and deeply interesting one of "phthisis pulmonalis," a subject which has, perhaps, occupied the attention of the profession and called forth more earnest, active effort for its solution for centuries, than any other subject in medicine; and yet its ravages have not been checked to any considerable extent, for it destroys more life in almost all countries than any other disease. The deaths from consumption in the United States of America are not less than 100,000 annually.

It is not that I have anything specially new to offer in etiology, prophylaxis or therapeutics that I select this as a subject of discourse, but a condensed review of what is more modern and practical, with suggestions based upon personal observation and experience as it relates to the general management of the disease, may be of interest to some of the members of this Association.

It is not my purpose to examine the various theories bearing on the pathology of consumption. That organization, anatomical and physiological peculiarities and inherited constitutional predisposition, are factors in favoring the development of tuberculosis, is evident beyond question. The dyscrasia of the scrofulous diathesis, inherited or acquired, with tendency to cheesy deposits, fits a soil for the growth of bacteria. In deference to popular opinion, we accept the teaching of Koch and other bacteriologists, that tuberculosis is the result of the life and growth of a microorganism in a soil favorable to its development. It is not proven, however, that phthisis pulmonalis is always tuberculosis. Clinical and pathological investigation seem to show that phthisis pulmonalis is sometimes tuberculous, and sometimes non-tuberculous.

I think most physicians who have had long clinical experience have, from time to time, observed cases of good family and personal history,

without predisposition inherited or acquired to scrofulous or tuberculous disease, come suddenly down, with cause apparent, from broncho- or croupous pneumonia, and pass rapidly into consolidation, caseation, disintegration and formation of cavities, general emaciation, progressive debility and death. Then we have the more chronic fibroid phthisis, the prime cause sometimes being from inflammatory pneumonic consolidation, and at other times from the daily inhalation of irritating particles of matter, metallic or earthy. This cause of phthisis has been productive of fearful mortality in certain employments.

While it is shown that numerous bacilli are present in the forms of phthisis which appear to have a specific cause independent of true tubercle, it is not proven that the bacilli found are the tubercle bacilli of Koch. Drs. Gibbes and Shurly, who have been doing good bacteriological work, diagnosed the matter by feeding several guinea pigs with the sputum filled with bacilli from a case diagnosed as phthisis during life, but which an autopsy showed to have been a case of broncho-pneumonia, with disintegration of, and large cavities in lungs. The guinea pigs inoculated with matter swarming with bacteria, suffered from abscesses at point of inoculation, but none suffered from tuberculosis.

We are not yet ready to accept the doctrine of the positive minds who have attempted to settle the question for all.

Germain Sée says: "The unity of phthisis comprises all acute and chronic manifestations. There exists no dualism between tubercle and caseous pneumonia; no distinction between tuberculous phthisis and inflammatory phthisis." We believe that this is still an open question.

It is well known that all pulmonary tuberculosis is the result of the action of the bacillus of Koch upon anatomical structure rendered vulnerable by reason of inherited tendency, the scrofulous diathesis, caseous pneumonia with cheesy deposits, lessened vitality with enfeebled circulation and respiration, we shall feel the importance of carefully studying preventive measures. Prophylaxis is all-important.

If we accept the teaching of Virchow and Niemeyer, that caseous pneumonia and miliary tuberculosis are distinctive diseases, and remember the

great liability to tuberculosis in the metamorphoses of tissue from caseous pneumonia, our course of action will be little influenced by the technical question.

Whatever the pathogenesis of tuberculosis may be, it is evident that the strumous diathesis is frequently the predisposing cause. The relation of the two conditions is too evident to be questioned, and as struma manifests itself, many times, in the earlier periods of life, and is often due to faulty dietetic and hygienic management, we cannot too much feel the vital importance of correcting a condition which warns of approaching danger; for when the specific microorganisms enter the blood, the corpuscles or leucocytes are destroyed in the unequal warfare of such enfeebled constitutional conditions.

Noxious microorganisms may, and do, enter the body without producing disease. Man is continually exposed to infection by the bacillus tuberculosis. Heller, from microscopical preparations, estimates that in a single expectoration, on an average, 3,000,000 bacilli are discharged. Sputa, swarming with bacteria, is deposited on walks, floors of cars, boats, school-rooms and public halls. Such sputa soon dries, forms a floating dust full of poisonous microbes to which all are exposed, but only a few of the many are susceptible to their influence. Microbes, when introduced into the system, may or may not result in structural change or disease; the soil may be favorable or unfavorable. It is not yet determined what the chemical conditions of the solids and fluids of the body are in, when the tuberculous cachexia is developed. The child may inherit the diathesis or predisposition to susceptibility to tubercular disease; yet, under most favorable environment, never contract tuberculosis. Cancer and syphilis are transmitted from parent to child. Children are born with these diseases well developed, but there is little evidence that tuberculosis is inherited—the diathesis is inherited, not the specific disease.

We do not fully understand what the condition of the system is, which we call the tubercular cachexia. It is probably something more than debility, lowered vitality, or anatomical defect, but a peculiar change in the fluids or secretions of the body which favors the development and destructive work of the tubercle bacillus when it finds entrance into the system. It has been observed in laboratory experiments that certain conditions are essential in cultivating bacteria.

Pasteur relates that when he used agar-agar with 4 per cent. of glycerine as a culture medium, the tubercular bacilli developed rapidly, but when he added 8 per cent. instead of 4 per cent of glycerine to the medium, the growth of germs ceased. Then may we not hope that, in the progress of scientific investigation and experiment, the definite cause of susceptibility to tuberculosis may be made

out, and means devised to destroy such susceptibility, and to render the tissues of the body unfit for the life and growth of these microorganisms?

It is probable that tuberculosis is sometimes acquired from the flesh and milk of tuberculous animals. The weight of opinion seems to favor this belief. It is the duty of physicians, individually and collectively, to influence, so far as possible, the Department of State Medicine, to create and enforce strict regulations against the spread of tuberculosis, so far as it can be done. I will not particularize how this should be done. The measures to be taken are important and varied, and suggest themselves to the physician and sanitarian.

Our duty as physicians, is the important one of guarding and guiding, so far as we can, the child, the youth and the man, against inherited predisposition to phthisis, as well as to correct, so far as possible, constitutional defects, and conditions of health leading to a susceptibility of danger almost ever-present. It becomes us to inquire what are the conditions which precede the infection, and the causes which produce the condition.

It is not my purpose to examine the various theories and alleged causes which precede tuberculosis, such as abnormalities of organization with faulty development of chest and lungs, and lack of anatomical and physiological balance in the vital organs, but to causes which are susceptible to influence by hygienic, dietetic and medicinal means.

The child and the youth with low vital force, with cardiac power below the average normal, with relatively small volume of lung and feeble respiratory system, will necessarily suffer from adynamic catarrhs, glandular congestions and inflammations, defective assimilation and nutrition, and this condition strongly predisposes to phthisis. The importance of nutrition as a preventive of consumption cannot be exaggerated; but with faulty organization and feeble respiratory function, how can good nutrition be maintained?

Physical training for the purpose of developing the chest walls and respiratory muscles, enlarging the volume of the lungs, thereby stimulating and developing the circulation of blood throughout the system, blood which has been more completely arterialized in the lungs, will do more than anything else to favor digestion, assimilation and nutrition. Training, systematically and perseveringly practiced, will often change the flat, narrow-chested, poorly nourished, feeble youth into the large-chested, ruddy, vigorous man.

The physiological-therapeutical effects of increased chest development with lung expansion and volume, thereby increasing the activity of intra-pulmonary circulation and oxidizing a larger number of blood corpuscles, renders active the nutrition of pulmonary tissue—not alone of pulmonary tissue, but a general tonic effect is pro-

duced upon the nervous system; digestion and cellular nutrition are improved; the vital power is raised, and alimentation, the most important element in the prevention and cure of phthisis, is increased.

All observers know that faulty nutrition and wasting usually precede phthisis. Dr. Horace Dobell, in his work on the "True First Stage of Consumption," gives expression to the belief that the wasting or inanition preceding tuberculosis should be considered as belonging to the first stage of the disease.

Next in importance to nutrition is vigorous circulation of blood, pure air and sunlight.

It was an interesting and instructive experiment made by a physician a little time ago—I cannot give his name or the date of the article—showing the influence of favorable conditions in preventing the development of tuberculosis. He inoculated, I think it was two dozen rabbits with the tubercle bacillus. One-half the number were confined in pens with not good chance for sunlight nor active exercise, nor with supply of food exactly suited to their wants. All died from tubercular disease. The other half were turned into a field, favored with fresh green grass, strong light, and opportunity for the freest exercise, with the result of only one falling a victim to tuberculosis; all the others remained healthy, notwithstanding the true tubercle bacillus had been introduced into their bodies. We should not forget this lesson, for it is in harmony with what has so often been observed in man. The vigorous and well nourished, with favorable environment, rarely fall victims to tuberculosis from infection when closely exposed, sometimes for years. Then let us remember that preventive measures must be in the keeping of the general health above the grade of susceptibility to the microbic influence; keep the soil unfavorable to the development and growth of bacilli.

The scope of this paper will not allow me to attempt to note all or many of the various dietetic and hygienic measures to be observed as contributing to the raising of the standard of health and creating an immunity from the disease.

Climatic influences are efficient aids in prophylaxis of phthisis. When, from hereditary predisposition, faulty anatomical and physiological condition, the thoracic cavity small, and respiratory power feeble, a change of climate should be made from the lower sea level to high altitudes.

An elevated, cool, dry region should be selected for such cases. In high altitudes, respiratory activity is much increased, and portions of the lung tissue little used on low levels, are brought into activity. Both children and adults who live in high mountainous regions have proportionately larger chests and lungs than those who live in low altitudes; this has been shown from repeated observation. Dr. Francis, of the Bengal Army,

states, after extended observation, that the lungs are smaller in Europeans in India than the European standard. The lesson from this is practical and should be kept in mind. Low temperature in high altitudes, with dry atmosphere, is most favorable. Cold stimulates to more active exercise, with increased respiration and blood circulation. The appetite for fatty, nitrogenous food is increased, foods specially adapted to the prevention as well as to the arrest of consumption. The spores of tubercular bacteria are tenacious of life, resist almost all influences for their destruction, maintain life for hours in water at the boiling point. Extreme cold and perfect dryness are without influence, then it cannot be claimed that high altitude has germicidal influence, but immunity, if it comes, is from improved physiological conditions.

Dryness and purity of the air are important, perhaps the most important, factors in prophylaxis. Air tested in the higher mountains of Switzerland showed no bacteria, while the same volume of air in Paris contained 7,000.

The atmosphere of high elevations is both drier and purer than that of low levels, and when free from microbes, it must greatly favor prophylaxis, and efficiently aid in the recovery from incipient phthisis. The air by the sea side, or in the valleys when sparsely settled, may be as pure and as clear, may be as favorable to the consumptive in the advanced stage of the disease as the rarefied air of high altitudes, though it is probable that the dry, rarefied air of the mountains is inimical, in some degree, to the development and growth of microorganisms.

Altitude in advanced consumption often acts unfavorably, particularly as it relates to the congestive, the hemoptotic, and the irritable conditions.

We have been too much inclined to send all cases of confirmed phthisis to certain localities according to the prevailing fashion, without carefully scrutinizing every condition likely to be influenced by denser or rarefied air, by temperature, by physical comfort and mental and emotional happiness.

It is all-important that the consumptive shall live an outdoor life, and the climate and conditions of the locality must be such that a life much in the open air can be enjoyed. While altitude has an important influence, the most recent study of the subject seems to show that the mortality from pulmonary phthisis is not exactly graded by elevation, though largely influenced by it.

Dr. Schroeter, carefully studying the exact official statistics of Switzerland bearing upon the mortality of consumption for eleven years, states: "The annual mean of deaths caused by pulmonary tuberculosis is 2.31 to 1,000 living inhabitants." In an altitude of 200 to 400 metres, there were 112 deaths from tuberculosis in 1,000;

from 400 to 700 metres, 105 deaths; from 700 to 900 metres, 106 deaths; from 900 to 1,200 metres, 92 deaths; above 1,200 metres, 71 deaths. The death-rate in great altitudes falls low, 71 in 1,000; but there are other influences than altitude of which we should not lose sight. Density of population, and industrial occupations indoors, greatly increase mortality. The higher elevations are more sparsely settled, and the people live an active outdoor life; this, perhaps, in itself would account largely for the difference in the rate of mortality in different altitudes.

The contagiousness of tuberculosis is now so well established, and the more common method of infection made so apparent from a careful study of the subject, that it requires little argument to sustain the statistical facts bearing on the question of prophylaxis, and as the methods of prophylaxis are the methods for the arrest of the disease in its early stage, they can not be too carefully studied.

Cornet, whose investigations have been extensive, and apparently carefully and scientifically made, concludes, that tuberculous consumption is very largely communicable by dried sputum, in the form of dust floating in the air, and taken into the air passages by inhalation. He accounts for the greater prevalence of pulmonary tuberculosis over other forms of the disease in this way, and questions whether the lungs have any especial predilection for tubercular infection.

Remembering how tubercular bacilli are most likely to gain access to the body, we should ever keep in mind the importance of avoiding the ordinary sources of danger.

Dr. Bowditch, of Boston, more than thirty years ago, in studying the predisposing and, as he believed, the exciting causes of consumption, showed clearly that the most common predisposing cause as it relates to climate and locality, is low temperature and humidity, with soil saturation; the most marked predisposing and exciting causes, other than cold and dampness, bad air from overcrowding and faulty nutrition. All subsequent study has confirmed the wisdom of this earlier teaching.

In the knowledge of the contagiousness of tuberculosis we more clearly understand that density of population and industrial occupations so largely increase mortality from phthisis. Then it would seem vitally important in the management of consumption, particularly in its earlier stage, when any hope exists for arresting its progress or effecting its cure, to radically change, so far as possible, all unfavorable environments so as it relates to climate, to habits of life and sanitary influences. Individuals living near the sea level should change to mountain regions and live an active outdoor life if strength will permit. A larger portion of cases of advanced phthisis will do better in high altitudes, with cold, clear, dry

atmosphere than in warmer lower levels; but there are many exceptions to this rule.

The high, cold mountain region of winter cannot be favorable to the nervous, sensitive man or woman, who has led a life largely in doors, debilitated from disease. In those suffering from cardiac weakness, functional or organic, and of those of hæmorrhagic diathesis, such winter climate should be avoided.

In advanced phthisis with high and marked change in pyrexia, and much destruction of lung tissue, and in laryngeal phthisis, as well as in the old and the very young, a milder climate in winter must be advised.

Cases specially unfavorably influenced by the cold of high altitudes are those of defective heart power and specially sensitive to cold, and not of sufficient vitality to take active exercise out of doors; such cases are not likely to do well anywhere, but they are more comfortable, and perhaps live as long or longer in a warmer, denser atmosphere, particularly as it relates to the colder seasons. Too much stress cannot be put upon the importance of a life out of doors. I have repeatedly seen the most remarkable recoveries in unpromising cases from a life on the road by horseback or carriage.

A large proportion of cases of phthisis in the adult male feel the stern necessity of doing something for their support as long as it is possible for them to do so. Persuade the worker indoors to lead the life of a country peddler, or to go to the country, buy produce to ship to market, or do anything which will contribute to his support and keep the mind employed, and give him pure air and strong sunlight. Such a life, with frequent change in diet, gives appetite for better food and greatly favors digestion and nutrition. The skin grows brown and the blood redder, the mind happier in the sense of self-support, and hope and courage grow accordingly. The law of necessity often favors recovery. I have seen more cases do well when leading such a life for a livelihood than I have seen where fortune allowed a life of luxurious invalidism. It is folly, worse than folly to advise the sufferer to go to a popular resort for the consumptive when he has not, and cannot obtain the means for his support. It is cruel to allow him to feel that his life depends upon what he cannot have. It is not only important that respiration shall be carried on in free pure air all day, but all night as well; the day exposure favors freedom of air circulation at night.

It is not my purpose in this brief address to say much of the general management of phthisis, or to collate what has been said by master minds regarding it, but only to emphasize what seems to me most important.

In therapeutics we have made little advancement in the last thirty years, though pharmacy

has given us tonic combinations like the compound hypophosphites, more elegant and less objectionable to the taste and the stomach than the remedies and mixtures of earlier times. Arsenic is now more used than formerly and is an important aid in increasing assimilation and nutrition when judiciously used. Cod liver oil and fatty foods justly hold full favor when they can be assimilated. Medicinal inhalations, after much trial, have proved of little value.

Each case is a study in itself and treatment of individual cases must often widely differ. We have no specifics, and bearing in mind scientific experiment as it relates to the destruction of bacilli outside the body, we can dismiss as useless microbicidal treatment. All effort in that direction has proved futile and is more than likely to in the future.

Progress has been made in dietetics. The importance given to food more largely animal, and the methods of its preparation, like depriving beef wholly of its water and reducing the same to a powder so that it can be taken freely when meat will not be eaten, is a step in advance.

Predigested beef and milk and pancreatic preparations of fatty foods, so essential in wasting disease, greatly aid nutrition when digestion is impaired.

It is a noteworthy fact that tuberculosis is seldom found in carnivora living in their natural state; though wild beasts confined in cages and fed upon the flesh of domestic animals liable to be tuberculous contract the disease. Herbivorous animals are easily inoculated with the tubercle bacillus. Reasoning from analogy, we should expect to see less tuberculosis in classes living principally upon animal food, and this holds true.

In Iceland and the Faroe Islands, where the inhabitants live almost exclusively upon animal diet, consumption is almost unknown. Experience, I think, has shown that consumptives who can live largely upon animal food, meats, animal oils and fats, milk and eggs, do best. In the advanced stage of phthisis with high pyrexia, lessened volume of lung from destruction of tissue interfering with oxidation of heavy nitrogenous food, a simple diet of milk, soups, kumyss, malt extract, glycerine, etc., is indicated.

The dietetic management of phthisis is more important than the therapeutic, and should receive more careful supervision from the physician; he should supervise the feeding, the methods of nutrition, as fully as the medicinal treatment, and not leave the more important to the badly educated appetite of the patient, nor to the ignorance of friends and nurses. Feeding must be prescribed and nutrition enforced. A paper on "Food in the Treatment of Pulmonary Consumption," by Dr. Solis-Cohen, of Philadelphia, published in THE JOURNAL, February 8, 1889, is full of pertinent suggestions, clearly and forcibly stated.

Jaccoud's teaching, than which little is better, as it relates to therapeutical management, should be studied by the inexperienced practitioner, particularly the advice to avoid the use of cough syrups, opiates and palliatives, which lessen appetite, impair digestion and nutrition. His earnest recommendation to use persistent counter-irritation over diseased parts, to lessen cough instead of giving anodyne cough mixtures, is to be commended.

Something can be done to relieve harassing cough and not disturb nutrition by the inhalation from respirators charged with volatile anesthetic and antiseptic agents, like creosote, iodized carbolic acid, bromine, menthol and camphor mixtures.

There is diversity of opinion as to the use of alcoholic drinks in phthisis. Sometimes they are indicated and are efficient in creating appetite and promoting digestion and nutrition. Many will take a glass of good ale or porter with real relish and marked benefit. Others, females in particular, can take whisky in milk, or good, sound red wine at times with good effect, while in other cases stimulants are contraindicated; the appetite is lessened and digestion impaired from their use.

It will not be profitable to review what has been written relative to the method of treating tuberculosis by Prof. Koch. The literature upon the subject is now voluminous, but most of it is of little value. Sufficient time has not elapsed to determine whether or not it will be the method of the future for the treatment of pulmonary tuberculosis.

The later reports from the more competent experimenters are not specially promising.

If the creating of the so called lymph is so difficult, and its use so dangerous that it cannot be entrusted to scientific physicians of all countries, it will be a long time before the value of the discovery will be determined.

It is now six months since the announcement of an important discovery was made, and why should so much secrecy surround it? We cannot believe, as has been asserted, that it is for purposes of money-making by a great and progressive government, or that scientific physicians of worldwide reputation would join government officials in financial speculation in material only used in the relieving of physical and mental anguish, and in the saving of human life.

It is important that great care should be taken to have the matter tested by careful, competent men, but the production of the material and its use can be safely entrusted to other than German physicians.

In the giving out of the lymph for experimental purposes, the supply being limited, it was properly restricted to hospital use. The dishonest acquisition and use of it for personal advertisement in public print cannot be too severely con-

denmed. No physician with sufficient self respect to regard the good opinion of the profession at large will allow himself to be advertised for personal gain in such a way.

The advertising physician is found in the hospital as well as in private practice, and "some of them are making good and ingenious use of the popular interest in the subject to bring their names into daily notice and prominence." Such practice, whenever it occurs, should be frowned upon.

ORIGINAL ARTICLES.

AN ANALYSIS OF THE STATISTICS OF FORTY-ONE THOUSAND FIVE HUNDRED CASES OF EPIDEMIC INFLUENZA.

Read before the American Academy of Medicine, Philadelphia, December 4, 1890.

BY BENJAMIN LEE, A.M., M.D., PH.D.,

SECRETARY OF THE STATE BOARD OF HEALTH OF PENNSYLVANIA.

It is not difficult to understand why, in the extreme south eastern portion of Europe, doubts should have been entertained as to the diagnosis of the disease, which during the past year has not only overspread that continent, but crossing the ocean, has swept over this country so generally and attacked the population so universally that we are justified in calling it a *pandemic*.

It is evidently due to the fact that one of the prominent symptoms, which is, however, by no means an essential symptom, namely: coughing and sneezing, indicating catarrh of the air passages, has been mistaken in the minds of the people, and to some extent also of the medical profession, for the disease itself. To such an extent is this true, that one medical author of considerable reputation has designated it *Epidemic Acute Bronchitis*.

The first intimation which we had of its presence in Europe was that all St. Petersburg was coughing and sneezing. And so, for many weeks, almost the only references to the spread of the disease on that continent contained allusions, usually of a jocular character, to this peculiar feature of a certain proportion of the cases. People appeared to look forward to its appearance on this side the ocean as an experience, which, on the whole, would constitute a mild amusement, rather than an occasion of suffering, distress, terror and death. A very few weeks, however, sufficed to convince both the public and the profession that influenza meant a good deal more than a bad cold in the head.

Discovering this fact, and observing the serious involvement of the nervous system in a large percentage of the cases, the inquiry suggested
